LOCAL $L$-FACTORS AND GEOMETRIC ASYMPOTOTICS FOR SPHERICAL VARIETIES

YIANNIS SAKELLARIDIS AND JONATHAN WANG

Abstract. Let $X$ be an affine spherical variety, possibly singular, and $L^+X$ its arc space. The intersection complex of $L^+X$, or rather of its finite-dimensional formal models, is conjectured to be related to special values of local unramified $L$-functions. Such relationships were previously established in [BFGM02] for the affine closure of the quotient of a reductive group by the unipotent radical of a parabolic, and in [BNS16] for toric varieties and $L$-monoids. In this paper, we study this intersection complex for the large class of those spherical $G$-varieties whose dual group is equal to $\tilde{G}$. We calculate the pushforward of this complex to the arc space of the toric variety $X/\mathcal{N}$ (where $\mathcal{N}$ is a maximal unipotent subgroup) and the stalks of its nearby cycles on the horospherical degeneration of $X$. We formulate the answer in terms of a Kashiwara crystal, which conjecturally corresponds to a finite-dimensional $\tilde{G}$-representation determined by the set of $B$-invariant valuations on $X$. We prove the latter conjecture in many cases. Under the functions–sheaves dictionary, our calculations give a formula for the Plancherel density of the IC function of $L^+X$ as a ratio of local $L$-values for a large class of spherical varieties.

1. Introduction

1.1. Arc spaces and their IC functions. Let $\mathbb{F}$ be a finite field, $G$ a connected reductive group over $\mathbb{F}$, and $X$ an affine spherical $G$-variety. The formal arc space $L^+X$ is the infinite-dimensional scheme that represents the functor $R \mapsto X(R[[t]])$, and it is singular, if $X$ is. However, its singularities at “generic” $\mathbb{F}$-points (namely, arcs $\text{Spec} \mathbb{F}[t] \to X$ which generically lie in the smooth locus $X^{sm}$) are of finite type, according to the theorem of Grinberg–Kazhdan and Drinfeld, and this allows one to define an IC function [BNS16], that is, the function that should correspond under Frobenius trace to the “intersection complex” of $L^+X$. This is a
function $\Phi_0$ on $X(\mathfrak{o}) \cap X^{\mathrm{sm}}(F)$ (where $\mathfrak{o} = \mathbb{F}[t]$ and $F = \mathbb{F}(t)$), and it was conjectured in [Sak12] (before the rigorous definition of this function was available) that it is related to special values of $L$-functions. Such a relation was established in [BNS16] for toric varieties and certain group embeddings, termed $L$-monoids, generalizing the local unramified Godement–Jacquet theory. One goal of the present paper is to prove such relations, for a different and broad class of spherical varieties.

In order to compute the IC function, we need to work with finite-dimensional global models of the arc space, or rather, the arc space over the algebraic closure $k$ of $F$ — let us base change to $k$ from now on, without changing notation. However, for motivational purposes, let us here pretend that $L^+X$ were already finite-dimensional, and the intersection complex on it were defined as a $\mathbb{Q}_\ell$-valued constructible (derived) sheaf, for some prime $\ell$ different from the characteristic of $F$. We would normalize such a sheaf to be constant in degree zero over the arc space $L^+X^{\mathrm{sm}}$ of the smooth locus, and we would normalize the intersection complex of a substratum $S \subset L^+X$ of codimension $d$ to be $\mathbb{Q}_\ell(\frac{d}{2})$ on its smooth locus, where $\mathbb{Q}_\ell(\frac{1}{2})$ denotes a chosen square root of the cyclotomic Tate twist.

Let $B \supset N$ be a Borel subgroup of $G$, and its unipotent radical, and consider the invariant-theoretic quotient $X//N = \mathrm{Spec} \ k[X]^N$, which is an affine embedding of a quotient $T_X$ of the Cartan $T = B/N$. In this paper, we restrict ourselves to varieties where $B$ acts freely on an open subset $X^{\circ}$ of $X$, so let us already make this assumption for notational simplicity. Then $T_X = T$, and we fix a base point to identify $T$ as the open orbit in $X//N$. In fact, our assumption on $X$ is stronger, requiring that the (Gaitsgory–Nadler) dual group of $X$, $\check{G}_X$, is equal to the Langlands dual group of $G$ — this condition is equivalent\(^1\) to the following:

\begin{equation}
\text{\textbf{B acts freely on $X^{\circ}$, and for every simple root $\alpha$, if $P_\alpha$ is the parabolic generated by $B$ and the root space of $-\alpha$, the stabilizer of a point in the open $P_\alpha$-orbit $X^{\circ}P_\alpha$ is a torus (necessarily one-dimensional).}}
\end{equation}

The pushforward map $\pi : X \to X//N$ induces a map between arc spaces. Under our assumptions, the “generic” $L^+T$-orbits on the arc space of $X//N$, that is, those corresponding to arcs whose generic fiber lands in the open $T$-orbit, are naturally parametrized by a strictly convex (i.e., not containing non-trivial subgroups) submonoid $\mathfrak{c}_X \subset \check{\Lambda}$ of the cocharacter group of $T$, with $\check{\lambda} \in \mathfrak{c}_X$ corresponding to the image $t^{\check{\lambda}} := \check{\lambda}(t)$ of a uniformizer (acting on a fixed base point of $X//N$). The pushforward $\pi_! IC_{L^+X}$ of the IC sheaf is $L^+T$-equivariant, and under Frobenius trace translates to a $T(\mathfrak{o})$-invariant function on $X//N(\mathfrak{o}) \cap T(F)$, which will be denoted by $\pi_! \Phi_0$. Explicitly,

$$\pi_! \Phi_0(t) = \int_{N(F)} \Phi_0(tn)dn,$$

i.e., the integral of the IC function $\Phi_0$ over the fibers of the map $X(\mathfrak{o}) \to X//N(\mathfrak{o})$, where the Haar measure on $N(F)$ is so that $dn(N(\mathfrak{o})) = 1$.

This integral is really a finite sum, hence makes sense over $\mathbb{Q}_\ell$, but let us for simplicity choose an isomorphism $\mathbb{Q}_\ell \simeq \mathbb{C}$, such that the geometric Frobenius morphism $\text{Fr}$ acts on the chosen half-Tate twist $\mathbb{Q}_\ell(\frac{1}{2})$ by $(-q\frac{1}{2})$. Our results and conjectures are best expressed under the assumption that $X$ carries a $G$-eigen-volume form; we will assume this for the rest of the introduction. The absolute value of the volume form is a $G(F)$-eigenmeasure on $X(F)$, whose eigencharacter we will denote by $\eta$. (We will not impose this assumption on the rest of the introduction.)

\(^1\)To be precise, we are referring to the modification of the Gaitsgory–Nadler dual group described in [SV17], because the Gaitsgory–Nadler dual group would be $\check{G}$ even if the stabilizers were normalizers of tori. This small distinction is important, and such cases (for example, $O_n/\GL_n$) are not expected to be directly related to $L$-functions, and not included in the present paper.
paper, but see Remark 5.4.4.) Then, one should consider the following normalized form of the above integral, analogous to the standard normalization of the Satake isomorphism:

\[(\eta \delta)^{\frac{1}{2}}(t) \pi_1 \Phi_0(t) = (\eta \delta)^{\frac{1}{2}}(t) \int_{N(F)} \Phi_0(tn)dn,\]

where \(\delta = |e^{2\rho_G}|\) is the modular character of the Borel subgroup.\(^2\)

Ideally, we would like to prove a conjecture such as the following. To formulate it, recall that \(T(\mathfrak{o})\)-orbits on \(T(F)\) are parametrized by Galois-fixed (that is, \(F\)-fixed) elements of \(\Lambda\).

**Conjecture 1.1.1.** There is a symplectic representation \(\rho_X\) of the \(L\)-group, \(\rho_X : \mathcal{L}G = \mathcal{G} \rtimes (\mathcal{F}_r) \to \text{GL}(V_X)\) (with \(V_X\) graded in degree 1), and a \(\mathcal{T}\)-stable polarization \(V_X = V_X^+ \oplus V_X^-\), such that the multiset \(\mathcal{B}^+\) of \(\mathcal{T}\)-weights of \(V_X^+\) belongs to \(\mathcal{C}_X\), and the pushforward of the IC function satisfies:

\[\eta \delta^{\frac{1}{2}}(t) \pi_1 \Phi_0 = \text{tr}_\mathcal{T}(\mathcal{F}_r, \mathcal{A}^* \langle \mathcal{A}(1) \rangle) \cdot \text{tr}_\mathcal{T}(\mathcal{F}_r, \text{Sym}^*(V_X^+)),\]

Here, for a \(\mathbb{Z}\)-graded representation \(V\) of \(\mathcal{T}\), the expression \(\text{tr}_\mathcal{T}(\mathcal{F}_r, V)\) denotes the function on \(\mathcal{A}^*\) whose value on \(\lambda\) is equal to the alternating trace of geometric Frobenius \(\mathcal{F}_r\) on the \((\mathcal{T}, \lambda)\)-eigenspace of \(V\).

From the point of view of number theory, the spherical varieties satisfying our assumption \(\mathcal{G}_X = \mathcal{G}\) give, in some sense, the most interesting periods, because they are associated to \(\mathcal{L}\)-values at the center of the critical strip. Indeed, one should always be able to choose the eigencharacter \(\eta\) such that the Frobenius morphism acts on \(V_X^+\) by permuting elements of a basis and scaling by \(q^{\frac{1}{2}}\). For example, when \(G\) is split and the colors (see below) of \(X\) are all defined over \(\mathcal{F}\), this permutation action should be trivial, and (1.3) should read:

\[\eta \delta^{\frac{1}{2}}(t) \pi_1 \Phi_0 = \frac{\prod_{\varphi \in \mathcal{B}^+} (1 - q^{-1}e^{\varphi})}{\prod_{\lambda \in \mathcal{B}^+} (1 - q^{-2}e^{\lambda})},\]

where \(\mathcal{B}^+\) is the multiset of weights, as in the conjecture, and \(e^{\lambda}\) denotes the characteristic function of the \(T(\mathfrak{o})\)-orbit of \(\lambda(t)\).

We will explain the relationship of this conjecture to various conjectures of arithmetic and geometric origin below. We do not quite prove the conjecture in all cases, but we determine the weights of \(\rho_X\) (in terms of \(X\)) and in the cases where \(\rho_X\) is minuscule, we prove the conjecture (Corollary 7.1.12). It is helpful to distinguish between the special case when \(X = \mathcal{H}\mathcal{G}^\text{aff}\) is the affine closure of a homogeneous quasi-affine variety, and the general case. In the special case, let us also assume, at first, that the monoid \(\mathcal{C}_X\) is freely generated with a basis \(\nu_1, \ldots, \nu_r\), so \(X/\mathcal{N}\) may be identified with \(\mathcal{A}^*\). This condition can always be achieved by passing to an abelian cover of \(\mathcal{H}\mathcal{G}\) and taking its affine closure, see §5.3. In that case, the generators \(\nu_i\) are the valuations associated to the colors, that is, the prime \(B\)-stable divisors of \(\mathcal{H}\mathcal{G}\).

**Theorem 1.1.2** (See §6.6). Assume that \(X = \mathcal{H}\mathcal{G}^\text{aff}\) satisfies the conditions above (\(T_X = T, \mathcal{G}_X = \mathcal{G}\) and \(\mathcal{C}_X \cong \mathcal{N}^r\) is free). Then there is a \((\mathcal{T} \rtimes \mathcal{F}_r)\)-representation \(V_X^+\) satisfying:

(i) the \(\mathcal{T}\)-weights of \(V_X^+\) belong to \(\mathcal{C}_X \setminus 0\);

(ii) the set of weights of \(V_X^+ \oplus (V_X^+)^*\) (without multiplicities) equals the set of weights of a \(\mathcal{G}\)-representation \(\rho_X\);

(iii) the dimensions of the weight spaces of \(V_X^+ \oplus (V_X^+)^*\) are invariant under the Weyl group \(W^\vee\) of \(G\).

\(^2\)We use additive notation for the character group \(\mathcal{A}\) of \(\mathcal{T}\), so \(e^\xi\) will denote the actual morphism \(\mathcal{T} \to \mathcal{G}_m\) corresponding to \(\xi \in \mathcal{A}\).
such that the pushforward \( \pi \cdot \Phi_0 \) of the IC function\(^3\) satisfies the formula (1.3) above.

In fact, we show more: we endow the multiset \( \mathcal{B} := \mathcal{B}^+ \sqcup (-\mathcal{B}^+) \) of weights of \( V_X \) with the structure of a Kashiwara crystal, see Theorem 1.3.2 below, and show that, if Conjecture 1.1.1 holds (equivalently, if the crystal is the one corresponding to the canonical basis of a finite-dimensional \( \mathfrak{g} \)-module), then \( \rho_X \) must be the direct sum of the irreducible \( \hat{G} \)-modules with highest weights in \( \hat{\Lambda}_G^+ \cap W\{\hat{\nu}_1, \ldots, \hat{\nu}_r\} \), each with multiplicity one (see Remark 7.1.11). In other words, the highest weights of \( \rho_X \) are the dominant coweights that are Weyl translates of the basis elements \( \hat{\nu}_1, \ldots, \hat{\nu}_r \).

As we already mentioned, Theorem 1.1.2 implies Conjecture 1.1.1 when \( \rho_X \) is miniscule. In particular, when \( H \backslash G \) is itself affine (equivalently, \( H \) is reductive: see [Lun73, Ric77]), we observe that \( \rho_X \) is always miniscule (Corollary 7.3.3). In this case Conjecture 1.1.1 was previously proved by [Sak13, Theorem 7.2.1], and Theorem 1.1.2 gives a geometric interpretation of this result.

For an example when \( H \backslash G \) is not affine:

**Example 1.1.3.** Let \( G \) be the quotient of \( \mathbb{G}_m \times \text{SL}_2^n \) by the diagonal copy of \( \mu_2 \), acting on \( X^\ast = \text{the quotient of SL}_2^n \) by the unipotent subgroup

\[
\left\{ \left( \begin{array}{cc} 1 & x_1 \\ 0 & 1 \end{array} \right) \times \left( \begin{array}{cc} 1 & x_2 \\ 0 & 1 \end{array} \right) \times \cdots \times \left( \begin{array}{cc} 1 & x_n \\ 0 & 1 \end{array} \right) \mid x_1 + x_2 + \cdots + x_n = 0 \right\}.
\]

Let \( \hat{X} \) be the affine closure of \( X^\ast \). Denoting by \( \hat{\mathbf{m}} \) the identity cocharacter of \( \mathbb{G}_m \), the monoid \( \mathfrak{c}_X \) is freely generated by the coweights

\[
\frac{\hat{\alpha}_1 + \hat{\alpha}_2 + \cdots + \hat{\alpha}_n + \hat{\mathbf{m}}}{2} \quad \text{and} \quad \frac{-\hat{\alpha}_1 - \hat{\alpha}_2 + \cdots + \hat{\alpha}_i - \cdots - \hat{\alpha}_n - \hat{\mathbf{m}}}{2}, \quad i = 1, \ldots, n,
\]

see Remark 2.1.2. These are miniscule weights of \( \hat{G} = \text{GL}_2 \times \text{det} \text{GL}_2 \times \text{det} \cdots \times \text{det} \text{GL}_2 \), and in that case Conjecture 1.1.1 holds, confirming an expectation of [Sak12, §4.5].

For the general case, \( X \) contains an open \( G \)-orbit \( X^\circ = H \backslash G \), which we will assume to satisfy the conditions of Theorem 1.1.2, except perhaps for the freeness of \( \mathfrak{c}_X^\circ \). In that case, the free monoid \( \mathbb{N}^D \), where \( D \) denotes the set of colors, maps through the valuation map to \( \mathfrak{c}_X^\circ \), and \( \mathfrak{c}_X \) is generated by its image and a minimal set \( D_{\text{sat}}(X) = \{ \hat{\theta}_1, \ldots, \hat{\theta}_d \} \) of distinct antidominant elements of the cocharacter group \( \hat{\Lambda} \) of \( T \). For each \( \hat{\theta}_i \), we let \( V^{\hat{\theta}_i} \) be the irreducible module of \( \hat{G} \) with lowest weight \( \hat{\theta}_i \), and assume that the eigencharacter \( \eta \) of the \( G \)-eigenmeasure on \( X(F) \) is of the form \(|\hat{e}|^\eta\) for some algebraic character \( \hat{\mathfrak{e}} \in \Lambda^W \).

Then:

\(^3\)Under the assumptions of the theorem, the restriction of the eigencharacter \( \eta \) to the colors \( \hat{\nu}_i \) is uniquely determined, see Remark 5.4.4.
Theorem 1.1.4 (See §6.6). In the above setting, if $V_{X^*}^+$ denotes the $\tilde{T}$-representation for $X^*_{\text{aff}}$ described in Theorem 1.1.2,\footnote{See §5.3 for a reduction to the case where $\zeta_{X^*}$ is free.} then the pushforward $(\eta\delta)^\sharp (t)\pi_!\Phi_0$ of the IC function for $L^+ X$ is given by (1.3) with

$$V_{X^*}^+ = V_{X^*}^+ \oplus \bigoplus_i V^{\tilde{h}_i} \left( \frac{\langle h + 2\rho_G, \tilde{h}_i \rangle}{2} \right) \left[ \langle h + 2\rho_G, \tilde{h}_i \rangle \right].$$

Notice that the set $D_{\text{sat}}(X)$ is stable under the Frobenius morphism. The action of Frobenius on the sum of $V^{\tilde{h}_i}$'s is the one obtained by identifying the Kashiwara–Lusztig canonical basis of this space with a set of subvarieties of the affine Grassmannian (see Section 7), and considering the Frobenius action on those.

The reader should compare the passage from Theorem 1.1.2 to Theorem 1.1.4 to the passage for $\text{nearby cycles}$, which is similar, however, the straightforward proof of [BNS16] uses the monoid structure on $X$ in a crucial way, and cannot be used here.

In §1.3 below we will describe the sheaf-theoretic statements of these theorems, in the setting of appropriate finite type models, the Zariski spaces for $X$ and $X/N$. Before we do that, let us relate the results above to conjectures in number theory and geometry.

1.2. The IC function and $L$-functions. The pushforward $\pi_!\Phi_0$ of the IC function (also known as “basic function”) under the map $X \to X/N$ admits various interpretations in terms of harmonic analysis, and, in particular, allows us to compute the Plancherel density of the basic function,

$$\| \Phi_0 \|^2 = \int_{T/W} \Omega(\chi) d\chi,$$

that is, the decomposition of its norm in the space $L^2(X(F))$ (with respect to the fixed eigenmeasure) in terms of seminorms $\| \cdot \| \chi$ that factor through eigenquotients for the action of the unramified Hecke algebra. The variable $\chi \in \tilde{T}/W$ above denotes the Satake parameter of such an eigenquotient, and $\Omega(\chi) = \| \Phi_0 \|^2 \chi$. (Here, we abuse notation and write $\tilde{T}$ for the unramified unitary dual of the torus $T(F)$, which is the maximal compact subgroup of the torus $\tilde{T}(\mathbb{C})$.)

The passage from $\pi_!\Phi_0$ to the Plancherel formula (1.7) is achieved through the theory of asymptotics, which is of geometric interest because of its relation to nearby cycles. For an affine spherical variety $X$ over a field $k$ in characteristic zero, one can define its horospherical degeneration (or asymptotic cone) $X_\theta$, by passing to the associated graded of the coordinate ring $k[X]$ as a $G$-module. A similar degeneration exists under some assumptions in positive characteristic, see §8.1. Under our current assumptions, its open $G$-orbit $X_\theta^*$ is isomorphic to $N \setminus G$, and the theory of asymptotics states\footnote{Currently proved under a slightly restrictive assumption that $X$ be “wavefront”, see [SV17].} that there is a canonical morphism $e_\theta^*: C^\infty(X^*(F)) \to C^\infty(X_\theta^*(F))$ which, roughly, describes the behavior of any function “at infinity”. Of interest to us is that the spaces $X/N$ and $X_\theta/N$ are canonically identified, and the corresponding pushforwards $\pi_!$ and $\pi_\theta!$ satisfy:

$$\pi_! = \pi_\theta! \circ e_\theta^*$$

(for appropriate functions, in order to ensure convergence), see [SV17, Proposition 5.4.6].

Let us, for simplicity, restrict ourselves to the case where (1.4) holds (in particular, $G$ is split), in order to present some explicit formulas. When restricted to $X_\theta^*$, the operator $\pi_\theta!$ is
the usual Radon transform, and its behavior on unramified functions is well-known; for example, the function $1_{X^\bullet}(\omega)$ maps to
\[ \prod_{\hat{\alpha} \in \Phi^+} \frac{(1 - q^{-1}e^{\hat{\alpha}})}{(1 - e^{\hat{\alpha}})}, \]
in the normalization of (1.4).\footnote{That is, we always multiply our functions by $(\eta \delta)^{\frac{1}{2}}(t)$; the character $\eta$ is immaterial here, since the functions are supported on the derived subgroup.} Inverting Radon transform, we can use (1.4) to compute the asymptotics of the IC function; for example, in the setting of (1.4),
\begin{equation}
(1.8) \quad (\eta \delta)^{\frac{1}{2}}(t)e_0^*\Phi_0 = \prod_{\hat{\alpha} \in \Phi^+} (1 - e^{\hat{\alpha}}) \prod_{\lambda \in \mathfrak{M}^+} (1 - q^{-\frac{1}{2}}e^{\lambda}) = \text{tr}_T(Fr, \wedge^*(\mathfrak{n})) \cdot \text{tr}_T(Fr, \text{Sym}^*(V^+_X)).
\end{equation}

Finally, Bernstein’s argument for the Plancherel formula, developed in [SV17], states that the Plancherel decomposition of $\Phi_0$ coincides with that of $e_0^*\Phi_0$,\footnote{To be precise, the argument states that this is the most continuous part of the Plancherel decomposition for $\Phi_0$, but arguing as in [Sak13] one can show that $\Phi_0$ is supported on the most continuous spectrum.} which by Mellin transform on $X^\bullet$ (with respect to the action of $T$) reads:
\begin{equation}
(1.9) \quad ||\Phi_0||^2 = \int_{T/W} \prod_{\lambda \in S^+} (1 - q^{-\frac{1}{2}}e^{\lambda}) d\chi = \int_{T/W} L(\chi, V_X; \frac{1}{2}) \frac{d\chi}{L(\chi, \mathfrak{g}/t, 0)}.
\end{equation}

Here $\mathfrak{S} = \mathfrak{S}^+ \cup (-\mathfrak{S}^+)$, and $L(\chi, V_X, 0)$ denotes a local unramified $L$-factor, while the density $\frac{d\chi}{L(\chi, \mathfrak{g}/t, 0)}$ is the unramified Plancherel measure for $G$.

The importance of (1.9) for arithmetic is that, according to the generalized Ichino–Ikeda conjecture of [SV17], the quotient of the Plancherel density of $\Phi_0$ by the Plancherel measure is related to the local Euler factor of the “$X$-period integral” of automorphic forms.

Such global applications are beyond the scope of this paper. Of more immediate interest here is the relation of the asymptotics map $e_0^*$ to nearby cycles: Since $X_0$ is obtained by degenerating the coordinate ring of $X$, there is an associated $G_0 \times G$-equivariant Rees family $\mathfrak{X} \to \mathbb{A}^1$ (depending, really, on the choice of a strictly dominant cocharacter into $T$), whose general fiber is isomorphic to $X$, and whose special fiber is isomorphic to $X_0$. This also induces a family of arc spaces, or loop spaces $L_{\mathfrak{a}}(\mathfrak{X}) \to \mathbb{A}^1$ where $L_{\mathfrak{a}}(\mathfrak{X})$ denotes the family of fiberwise loop spaces, not the loop space of $X$. In the context of an appropriate sheaf theory, to be denoted by $D$, this would give rise to a nearby cycles map:
\[ \Psi: D(LX) \to D(LX_0), \]
whose Frobenius trace is expected to recover the asymptotics map $e_0^*$.

After replacing $LX, LX_0$ by finite type models, the image of the nearby cycles functor has been computed by S. Schieder in the case where $X$ is a reductive group [Sch18, Sch16, Sch15]. In Theorem 8.3.6, we perform this calculation for the intersection complex of the global model $M_X$ of the arc space, for the spherical varieties under consideration, at the level of Grothendieck groups. We do this by relating the nearby cycles complex to $\pi IC_Y$, in a way that corresponds to the known relation [SV17, Proposition 5.4.6] between asymptotics and Radon transforms, thus confirming the expected relationship (Proposition 8.3.8). This resembles an analogous result [BFO12, Corollary 6.2] in the setting of character sheaves.

Finally, we explain how a formula like (1.9) relates to recent conjectures of Ben-Zvi–Sakellaridis–Venkatesh: According to those conjectures, the formula should follow by applying Frobenius traces on the endomorphism ring $\text{End}(IC_{L^X})$, where $k = \mathbb{F}$ denotes the algebraic closure, and the endomorphism ring is taken in the derived sense, in the dg-category of derived constructive
sheaves on $LX/L^+G$. (To be clear again, there are technical difficulties in defining intersection complexes in the singular setting, which we do not think have been fully resolved yet.) This conjecture identifies

$$\text{End}(IC_{L^+X}) \cong \mathcal{Q}_\ell[1]$$

for some symplectic representation $V_X$ as above. One can hope that our results can be related to this conjecture in both directions, namely, that relating our results to the study of such endomorphism rings will upgrade the $\hat{T}$-structure of Theorem 1.1.2 to a $\hat{G}$-structure, proving Conjecture 1.1.1, and contributing to the resolution of the aforementioned conjectures.

The conjectures of Ben-Zvi–Sakellaridis–Venkatesh, and the problems addressed by the present paper, can be formulated for more general affine spherical varieties, without the assumption that $\hat{G}_X = \hat{G}$. As already mentioned, from the point of view of number theory, this case is perhaps the most interesting one, as it corresponds to central values of $L$-functions. In the general case, the grading $V_X[1]$ appearing in the conjectural relation (1.10) needs to be modified.

1.3. Zastava spaces and the main theorems in terms of sheaves. From now on, we work over the algebraic closure $k$ of the finite field $\mathbb{F}$, or over an algebraically closed field $k$ in characteristic zero. When $X$ is defined over a finite field $\mathbb{F}$, we will keep track of Weil structures on our sheaves, which will always have the form of half-integral Tate twists, where, as mentioned, $(\frac{1}{2})$ denotes a fixed square root of the cyclotomic twist. The intersection complex of a $d$-dimensional scheme over $k$ will be understood to have stalks $\mathcal{Q}_\ell[f][d]$ over the smooth locus.

In order to replace the arc space by a model of finite type, we fix a smooth projective curve $C$ over $k$ (or $\mathbb{F}$). For an algebraic stack $\mathcal{X}$ and an open substack $\mathcal{X}^\circ \subset \mathcal{X}$, we will use

$$\text{Maps}_{\text{gen}}(C, \mathcal{X} \supset \mathcal{X}^\circ)$$

to denote the prestack that assigns to a test scheme $S$ the groupoid of maps $C \times S \to \mathcal{X}$ such that the open locus of points sent to $\mathcal{X}^\circ$ maps surjectively to $S$. Equivalently, these are the maps such that for every geometric point $\bar{s} \to S$, the restricted map $C \times \bar{s} \to \mathcal{X}$ generically lands in $\mathcal{X}^\circ$. Since $C$ is smooth, $\text{Maps}_{\text{gen}}(C, \mathcal{X} \supset \mathcal{X}^\circ)$ is an open substack of the prestack $\text{Maps}(C, \mathcal{X})$.

Given an affine spherical $G$-variety $X$ with open $G$-orbit $X^\bullet$ and open $B$-orbit $X^\circ$, we consider the following two models for the arc space of $X$:

- the Artin stack

$$\mathcal{M} = \mathcal{M}_X = \text{Maps}_{\text{gen}}(C, X/G \supset X^\bullet/G)$$

that we will simply refer to as “the global model”;

- the stack

$$\mathcal{Y} = \mathcal{Y}_X = \text{Maps}_{\text{gen}}(C, X/B \supset X^\circ/B)$$

that we will refer to as “the Zastava model”. In our setting ($X^\circ \cong B$), this turns out to be a scheme. Such a model is often referred to as the “local model” for reasons that have to do with factorization structures, but since this can create confusion with the genuinely local arc space, we will avoid such terminology.

For a discussion of why these are indeed formal models of the arc space (in the formal neighborhoods of suitable points), see Theorem 3.8.2, Lemma 3.5.4. Note that the choice of a Borel subgroup is immaterial, since $X/B$ can also be written as $(X \times B)/G$, where $B$ is the flag variety, with $X^\circ/B = (X \times B)^*/G$. 
We will also let $\mathcal{A}$ denote the analog of these models for the toric variety $X//N$, that is,

$$\mathcal{A} = \text{Maps}_{\text{gen}}(C, (X//N)/T \supset (X^\bullet//N)/T),$$

and notice that under our assumptions $X^\bullet//N \simeq T$. Fixing such an identification, for every $\chi \in \check{\chi}$ (the subset of $\Lambda_X =$ the character group of $X$ of those elements that are $\geq 0$ on $\mathfrak{c}_X$), the corresponding map $X//N \to \mathbb{G}_a$ gives rise to a morphism $\mathcal{A} \to \text{Maps}_{\text{gen}}(C, \mathbb{G}_a/\mathbb{G}_m \supset \mathbb{G}_m/\mathbb{G}_m) = \text{Sym} C$, the scheme of effective divisors on the curve. Thus, $\mathcal{A}$ can be thought of as the scheme of $\mathfrak{c}_X$-valued divisors. This scheme is well understood [BNS16]: its normalization is a disjoint union of partially symmetrized powers $C^\Psi$ of the curve, indexed by formal $N$-linear combinations $\Psi \in \text{Sym}^\infty(\text{Prim}(\mathfrak{c}_X))$ of the primitive elements of $\mathfrak{c}_X$.

The sheaf-theoretic analog of Theorems 1.1.2 and 1.1.4 is a statement about the pushforward of the IC sheaf under

$$\pi : \mathcal{Y} \to \mathcal{A}.$$ 

We will only compute $\pi_*\mathcal{IC}_Y$ in the Grothendieck group of sheaves on $\mathcal{A}$ (see Corollary 4.5.7), which is enough to determine the trace of Frobenius on stalks. The reason we do not compute the pushforward in the DG category (although this can be done in principle) is related to the fact that map $\pi$ is not proper. However, one can compactify $\pi$ by considering the compactified Zastava space

$$\mathcal{Y} = \text{Maps}_{\text{gen}}(C, (\overline{X}/N)/T \supset X^\circ/B),$$

where $\overline{X}/N$ stands for the stack $(X \times G//N)/G$, where $\overline{G//N} = \text{Spec} k[G//N]$ is the affine closure of $N\backslash G$.

The difference between $\mathcal{Y}$ and $\mathcal{Y}$ will account for the factor of $\prod_{\delta \in \Phi^+} (1 - q^{-1} e^\delta)$ in (1.3). The number theory-minded reader will recognize in this factor, in the case of $G = \text{SL}_2$, the Euler factor of the quotient between Eisenstein series obtained by summing over integral points of $N\backslash \text{SL}_2$, versus integral points of $N\backslash \text{SL}_2 = \mathbb{A}^2$. More generally, this is the factor that relates the “naive” and “compactified” Eisenstein series of [BG02], [BFGM02].

In Proposition 4.1.1 and Theorem 6.3.4 we prove:

**Theorem 1.3.1.** The map $\tilde{\pi} : \mathcal{Y} \to \mathcal{A}$ is proper and stratified semi-small.

This is one of the key technical results of this paper, because it allows us to get our hands on the pushforward of the intersection complex, without having a description of the complex itself. The assumption that $G_X = \tilde{G}$ is critical for the theorem: the analogous statement for the usual Finkelberg–Mirkovic Zastava space ([FM99, BFGM02]) is far from true.

The condition of being stratified semi-small is a condition on “smallness” of fibers, relative to a fixed stratification which, in this case, is the natural stratification of $\mathcal{A}$ by strata of the form

$$\mathfrak{c}_X^\Psi : \mathcal{A} \hookrightarrow \mathcal{A},$$

where $\mathfrak{c}_X$-valued divisors take a fixed set of values. (Here, $\mathcal{A}^\Psi$ denotes the open “disjoint” locus in a certain product of symmetric powers of the curve, corresponding to divisors of the form $\sum_{\lambda \in \mathfrak{c}_X} \sum_{i=1}^{N_\lambda} (x_i \mu)$ with all $x_i$’s distinct; we will denote by $\mathfrak{c}_X^\Psi$ the natural compactification.)

By the decomposition theorem, stratified semi-smallness ensures that $\pi_*\mathcal{IC}_\overline{Y}$ is a direct sum of irreducible perverse sheaves. By a factorization property of the $\mathcal{Y}$, this easily implies an expression for $\pi_*\mathcal{IC}_\overline{Y}$ of the form

$$\pi_*\mathcal{IC}_\overline{Y} \cong \bigoplus_\Psi \left( \bigotimes_\lambda \text{Sym}^{N_\lambda}(V_{X,\lambda}) \right) \otimes \mathfrak{c}_X^\Psi(\mathcal{IC}_{C^\Psi}),$$

where $\mathfrak{c}_X$-valued divisors take a fixed set of values. (Here, $\mathcal{A}^\Psi$ denotes the open “disjoint” locus in a certain product of symmetric powers of the curve, corresponding to divisors of the form $\sum_{\lambda \in \mathfrak{c}_X} \sum_{i=1}^{N_\lambda} (x_i \mu)$ with all $x_i$’s distinct; we will denote by $\mathfrak{c}_X^\Psi$ the natural compactification.)

By the decomposition theorem, stratified semi-smallness ensures that $\pi_*\mathcal{IC}_\overline{Y}$ is a direct sum of irreducible perverse sheaves. By a factorization property of the $\mathcal{Y}$, this easily implies an expression for $\pi_*\mathcal{IC}_\overline{Y}$ of the form

$$\pi_*\mathcal{IC}_\overline{Y} \cong \bigoplus_\Psi \left( \bigotimes_\lambda \text{Sym}^{N_\lambda}(V_{X,\lambda}) \right) \otimes \mathfrak{c}_X^\Psi(\mathcal{IC}_{C^\Psi}),$$

where $\mathfrak{c}_X$-valued divisors take a fixed set of values. (Here, $\mathcal{A}^\Psi$ denotes the open “disjoint” locus in a certain product of symmetric powers of the curve, corresponding to divisors of the form $\sum_{\lambda \in \mathfrak{c}_X} \sum_{i=1}^{N_\lambda} (x_i \mu)$ with all $x_i$’s distinct; we will denote by $\mathfrak{c}_X^\Psi$ the natural compactification.)

The decomposition theorem, stratified semi-smallness ensures that $\pi_*\mathcal{IC}_\overline{Y}$ is a direct sum of irreducible perverse sheaves. By a factorization property of the $\mathcal{Y}$, this easily implies an expression for $\pi_*\mathcal{IC}_\overline{Y}$ of the form

$$\pi_*\mathcal{IC}_\overline{Y} \cong \bigoplus_\Psi \left( \bigotimes_\lambda \text{Sym}^{N_\lambda}(V_{X,\lambda}) \right) \otimes \mathfrak{c}_X^\Psi(\mathcal{IC}_{C^\Psi}),$$

where $\mathfrak{c}_X$-valued divisors take a fixed set of values. (Here, $\mathcal{A}^\Psi$ denotes the open “disjoint” locus in a certain product of symmetric powers of the curve, corresponding to divisors of the form $\sum_{\lambda \in \mathfrak{c}_X} \sum_{i=1}^{N_\lambda} (x_i \mu)$ with all $x_i$’s distinct; we will denote by $\mathfrak{c}_X^\Psi$ the natural compactification.)
Theorem 1.3.2. Let $\mathcal{B}$ be a critical dimension, so $B$ is a Lie algebra $\mathfrak{g}$-representation of the maximal possible dimension for the central fiber $Y^\lambda$ and is equal to $\lambda$. We prove in Theorems 7.1.5 and 7.1.9: $\mathcal{B}$ is the affine closure of its open orbit (Theorem 5.1.5), and the monoid $\mathcal{C}$ is free. This reduction uses the action of the Hecke algebra, and resembles the calculation of the IC sheaf of reductive $L$-monoids in [BNS16], but is much harder. This reduction will be discussed in §1.4 below.

Hence for now let us focus on the case $X = \overline{X}^{\text{aff}}$, assuming that $\mathcal{C}$ is free. In that case, the maximal possible dimension for the central fiber $Y^\lambda$ will be called the critical dimension, and is equal to

$$\frac{1}{2}(\text{len}(\lambda) - 1),$$

where $\text{len}(\lambda) := \sum m_i \nu_i$ for $\lambda \in \mathcal{C} X$ written uniquely as $\sum m_i \nu_i$ in terms of our basis of $\mathcal{C} X$. Conjecturally, the set of irreducible components of $Y^\lambda$ of critical dimension, ranging over all $\lambda \in \mathcal{C} X$, should correspond to a canonical basis of the weight spaces of $\rho_X$ with weights in $\mathcal{C} X$.

We do not go quite as far in general, but we show that these irreducible components give rise to the aforementioned crystal, in the sense of Kashiwara [Kas93], over the Langlands dual Lie algebra $\mathfrak{g}$. Namely, let $\mathcal{B}_{X}^\bullet$, denote the set of irreducible components of the central fibers of critical dimension, so $\mathcal{B}^\bullet$ corresponds to a basis of $V^+_{X} := \bigoplus_{\lambda \in \mathcal{C} X} V_{X,\lambda}$. Formally define $\mathcal{B}_{X}^\bullet$ to be the “negatives” of $\mathcal{B}_{X}^\bullet$, so $\mathcal{B}_{X}^\bullet$ corresponds to a basis of the dual space $(V^+_{X})^\ast$. Let $\mathcal{B}_{X}^\bullet = \mathcal{B}_{X}^+ \cup \mathcal{B}_{X}^-$. We prove in Theorems 7.1.5 and 7.1.9:

**Theorem 1.3.2.** Let $X = \overline{X}^{\text{aff}}$ satisfy the assumptions of Theorem 1.1.2. The set $\mathcal{B}_{X}^\bullet$ has the structure of a semi-normal, self-dual crystal over $\mathfrak{g}$ such that the weights have the properties described in Theorem 1.1.2.

We conjecture:

**Conjecture 1.3.3.** The crystal $\mathcal{B}_{X}^\bullet$ is isomorphic to the unique crystal basis of a finite-dimensional $\mathfrak{g}$-module $V_{X}$. This would imply Conjecture 1.1.1.

Theorem 1.3.2 endows $V^+_{X} \oplus (V^+_{X})^\ast$, as we have defined it, with an action of an $\text{SL}_2$-triple corresponding to every simple root of $G$. These actions imply that the dimensions of the weight spaces are invariant under the Weyl group of $G$, which provides a kind of “functional equation” for $\pi_{\Psi_0}$. This functional equation can be seen as a geometric analog of the functional equation of the Casselman–Shalika method [Cas80, CS80, Sak13]. The content of Conjecture 1.3.3 is to show that these $\text{SL}_2$-triples satisfy the Serre relations.
The construction of the action of the SL\(_2\) corresponding to a simple root \(\alpha\) of \(G\) goes as follows: we factor \(X \rightarrow X/\mathbb{N}\) through \(X \rightarrow X/\mathbb{N}_{P_\alpha} \rightarrow X/\mathbb{N}\), where \(P_\alpha\) is the sub-minimal parabolic corresponding to \(\alpha\). Then the GIT quotient \(X_\alpha := X/\mathbb{N}_{P_\alpha}\) is a spherical variety for the Levi factor \(M_\alpha\). But now \(X_\alpha\) is (usually) larger than the affine closure of its homogeneous part \(X_{\alpha}^*\). The irreducible components of \(Y_X\) of critical dimension (i.e., elements of \(\mathfrak{B}_{X,\alpha}^*\)) will either go to irreducible components

(i) of \(Y_{X_{\alpha}^*}\) of critical dimension or

(ii) of \(Y_{X_{\alpha}} - Y_{X_{\alpha}^*}\) (not necessarily of critical dimension).

While the fibers of \(Y_X \rightarrow Y_{X_{\alpha}}\) are not necessarily irreducible, we show that the irreducible components of different relevant fibers can be canonically identified. Then we define the SL\(_2\)-action by analyzing the two cases above in the base \(Y_{X_{\alpha}}\).

Under our assumptions, \(X_{\alpha}^*\) is a torus torsor over \(\mathbb{G}_m \backslash \mathrm{PGL}_2\) and case (i) is an easy calculation. Meanwhile our study of non-canonical affine embeddings using Hecke actions shows that in case (ii) we always get a Mirković–Vilonen cycle (i.e., irreducible component of the \(\mathfrak{m}\)th-degree component of different relevant fibers can be canonically identified. Then we define the SL\(_2\)-action by analyzing the two cases above in the base \(Y_{X_{\alpha}}\).

To check the Serre relations, one can similarly reduce to a spherical variety \(X_{\alpha,\beta}^*\) for a Levi of semisimple rank two. There are only a handful such varieties (up to center) satisfying our assumptions — a small subset of the spherical (wonderful) varieties of rank two classified by Wasserman [Was96].

However, checking the Serre relations, even in a few cases, “by hand” does not seem to be easy, and we definitely do not have a conceptual proof of them; therefore, we refrain from attempting such a verification.

The remainder of the introduction will be devoted to describing the two most important elements in the proofs of the theorems above.

1.4. Reduction to canonical affine closure. We give an overview of how to reduce considerations of an arbitrary affine \(X\) with \(X^* = H \backslash G\) to the canonical affine closure \(X_{\text{can}} = \overline{H \backslash G}^{\aff}\).

There is a canonical map \(X_{\text{can}} \rightarrow X\), which induces an inclusion \(X_{\text{can}}(\mathfrak{m}) \cap X^*(F) \subset X(\mathfrak{m}) \cap X^*(F)\) of \(G(\mathfrak{m})\)-stable spaces and we are only concerned with arcs in the latter space. Of course, all points of \(X^*(F)\) are \(G(F)\)-translates of points in \(X_{\text{can}}(\mathfrak{m}) \cap X^*(F)\). It is a fact that if \(\theta \in \Lambda_G^\aff\) is antidominant and belongs to the monoid \(c_X\), then the action of the double coset \(G(\mathfrak{m})\theta G(\mathfrak{m})\) preserves \(X(\mathfrak{m}) \cap X^*(F)\). The idea for what follows is that we can obtain \(X(\mathfrak{m}) \cap X^*(F)\) by acting on \(X_{\text{can}}(\mathfrak{m}) \cap X^*(F)\) by \(G(\mathfrak{m})\theta G(\mathfrak{m})\) for \(\theta \in c_X := \Lambda_G^\aff \cap c_X\).

The Zastava model \(\mathcal{Y}\) lives over \(\mathrm{Bun}_B\) and does not carry a Hecke action. Thus to model the \(G(F)\)-action on \(X(\mathfrak{m}) \cap X^*(F)\) we must use the global model \(\mathcal{M} = \mathcal{M}_X\), which lives over \(\mathrm{Bun}_G\). The canonical map \(\mathcal{M}_{\text{can}} \rightarrow \mathcal{M}_X\) is a closed embedding. For \(\theta \in c_X \setminus 0\) (where we remind that \(c_X\) denotes the antidominant elements of \(c_X\)), let \(\mathfrak{m}_\theta^{\mathcal{G}_C}\) denote the Hecke stack over \(\mathrm{Bun}_G \times C\) with fibers isomorphic to \(\overline{G_\theta G}\), the closure of the \(L^+G\)-orbit in the affine Grassmannian corresponding to \(\theta\). In reality, we need a symmetrized (multi-point) version of the Hecke stack, but we only describe the case where there is one point on the curve in this introduction for simplicity. There is a well-defined map

\[
(1.12) \quad \mathcal{M}_{\text{can}} \times_{\mathrm{Bun}_G} \mathfrak{m}_\theta^{\mathcal{G}_C} \rightarrow \mathcal{M}_X
\]

modeling the \(G(F)\)-action, and we show (Theorem 5.1.1) that this map is birational onto its image. If we allow multiple points above, then the images of the corresponding Hecke actions stratify \(\mathcal{M}_X\).
Under the assumptions of the previous subsection, we show that $\mathcal{M}_{\text{can}}$ is irreducible (Corollary 5.6.3, so the study of $\text{IC}_{\mathcal{M}}$ reduces to the study of the Hecke action on $\text{IC}_{\mathcal{M}_{\text{can}}}$ and the determination of which of the strata above form irreducible components of $\mathcal{M}_\lambda$. For the latter, we need to understand the closure relations among the different strata (Proposition 5.6.1). When $c_{\lambda} = N^r$, the stratum corresponding to $\theta$ is contained in the closure of the stratum corresponding to $\theta'$ if and only if $\theta - \theta' \in c_{\lambda}$ (more generally, the closure relations are determined by the colors of $X$).

Ultimately, we need to understand how the Hecke action interacts with base change along $Y_X \to \mathcal{M}_\lambda$. This analysis is very similar to the considerations of [BG02] on how the Hecke stack interacts with flags on a $G$-bundle. On the central fiber, we are also naturally led to the consideration of semi-infinite orbits in $\text{Gr}_G$, which we describe in more detail below.

1.5. Semi-infinite orbits and dimension estimates. There is another way to understand the central fibers $Y_\lambda$ as subsets of the affine Grassmannian of $G$. Let us fix the point $v \in C$ that we take central fibers with respect to. Then a $k$-point of $Y_\lambda$ is a map $C \to X/B$ such that $C - v$ is sent to $X^\circ/B = pt$. Restricting to the completed local ring $\mathfrak{o}_v$ at $v$ gives a map $Y_\lambda \to LX^\circ/L^+$. If we fix a base point $x_0 \in X^\circ(k)$ to identify $X^\circ \cong B$, we get a map $Y_\lambda \to \text{Gr}_B$ and this turns out to be a closed embedding. The reduced image of the components of $\text{Gr}_B$ in $\text{Gr}_G$ are the semi-infinite orbits $S^\lambda(k) = N(F)t^\lambda G(\mathfrak{o})/G(\mathfrak{o})$. After passing to reduced schemes we get identifications $Y^\lambda_{\text{red}} = S^\lambda \times_{L^+} \text{Gr}_G$ and $Y^\lambda_{\text{red}} = S^\lambda \times_{L^+} \text{Gr}_G$ (see Lemma 4.1.2).

Semi-infinite orbits have an important meaning for the geometric Satake equivalence [MV07]: the fundamental classes of the irreducible components of the intersection $S^\lambda \cap \overline{G_{\theta}}$ of maximal dimension, the Mirković–Vilonen cycles, form (under this equivalence) the “canonical basis” for the $\lambda$-eigenspace of the irreducible $G$-module of lowest weight $\theta$.

Our analysis of the central fibers $Y_\lambda$ is founded upon the following argument from [MV07, §3]. The boundary $S^\lambda - S^\lambda = \cup_{\theta < \lambda} S^\theta$ is a hyperplane section for some projective embedding of $\text{Gr}_G$. Hence any closed subscheme of $\text{Gr}_G$ which intersects $S^\lambda$, also intersects its boundary in codimension one (unless already contained in the boundary). By inductively “cutting” by these hyperplanes, we prove:

**Theorem 1.5.1.** Let $X = X_{\text{can}}$ be as in Theorem 1.1.2. Let $b$ be an irreducible component of the central fiber $Y_\lambda$. Then

- $\dim b \leq \frac{1}{2}(\text{len}(\lambda) - 1)$,
- for a basis element $\nu_i$ of $c_{\lambda}$ (corresponding to a color), $Y^{\nu_i} = pt$,
- the inequality is an equality only if there is a sequence $\alpha_1, \ldots, \alpha_d$ of simple roots (with repetitions) such $\mathfrak{B} \cap S^{\lambda - \alpha_1 - \cdots - \alpha_d}$, is of dimension $\dim b - j$ (hence, also of critical dimension), and $\lambda - \sum_{i=1}^d \alpha_i = \nu$ for a color $\nu$.

The operation of hyperplane “cutting” can almost be thought of as the lowering operator for some $SL_2$-triple; unfortunately it is not quite precise enough, see Proposition 7.3.1.

If $X \neq X_{\text{can}}$, then we also show that if $b$ is an irreducible component of $Y_\lambda$ of critical dimension that is not contained in $Y_\lambda$, then $\lambda$ must be a weight of $V^\theta_i$ for one of the $\theta_i$ appearing in Theorem 1.1.4, and $b$ is birational to a Mirkovic–Vilonen cycle in $S^\lambda \cap \text{Gr}_{\theta_i}$. The latter correspondence comes from the Hecke action (1.12).
Let us comment on how the above relates to Theorems 1.3.1 and 1.1.4. Under our assumption that $c_X = N^r$, the space $Y_{X^{anc}}$ is irreducible. Then the dimension estimate in Theorem 1.5.1, together with a factorization property of $Y$, implies the “stratified semi-smallness” condition.

The irreducible components of $Y_{X^{anc}}$ of critical dimension correspond to a basis of $V^X_{anc}$. The other irreducible components of $Y_X - Y_{X^{anc}}$ of critical dimension correspond to Mirkovic–Vilonen cycles in $Gr^\lambda_G$, and these provide a basis for $V^\theta_G$ in Theorem 1.1.4 by geometric Satake.

1.6. Organization of the paper. In §2.1 we briskly review the salient combinatorics of spherical varieties and the classification of $G(\sigma)$-orbits of the loop space of $X$. In §3 we introduce the global models for the arc space of $X$ and their stratifications, explain why they are indeed models, and prove some foundational properties. In §4, we introduce the compactification of the Zastava model and define the central fibers of (compactified and non-compactified) Zastava models. Then we perform the comparison between $\pi IC_Y$ and $\bar{\pi} IC_Y$ that accounts for the “numerator” in the Euler product.

Sections 5 and 6 are the technical heart of this paper. In §5 we establish the closure relations for the global model $M_X$ and determine its irreducible components. This involves a study of the $G$-Hecke action on the global model, which also reduces the problem to the canonical affine closure, as explained earlier. In §6, we analyze the geometry of the central fiber and prove the crucial dimension estimates using the Mirkovic–Vilonen boundary hyperplanes of semi-infinite orbits. This allows us to prove Theorem 1.3.1.

In §7, we prove the aforementioned results on crystals. In §8, we combine the results of the preceding sections to compute the nearby cycles of the IC complex on the global model using a well-known contraction principle. Here we establish that nearby cycles does indeed correspond to the asymptotics map under the functions–sheaves dictionary.

In Appendix A, we collect various technical results concerning the stratification of the global model, some of which use the notion of generic-Hecke modification from [GN10]. In Appendix B, we review some properties of universally locally acyclic complexes that we could not find in the literature.

1.7. Index of notation.

In general, we will use calligraphic letters $D, V$ to denote standard combinatorial objects associated to spherical varieties in the literature, script letters $M, \mathcal{Y}, \mathcal{F}$ for algebraic stacks and sheaves, serif letters $Y, S$ for (ind-)schemes that are subspaces of certain loop spaces with respect to a fixed point $v \in |\mathcal{C}|$. The following table contains most of the notation used in this paper, except for notation defined and used locally.

- $k$: an algebraically closed field. The characteristic of $k$ can be zero or positive, but in the latter case we will impose some restrictions on our spherical varieties (see §2.1.3), to ensure that their geometry is similar to that in characteristic zero.
- $\mathbb{F}, \mathbb{F}_{\text{Fr}}$: At some points in this paper, $k$ is the algebraic closure of a finite field $\mathbb{F}$, and then $\mathbb{F}_{\text{Fr}}$ denotes the geometric Frobenius morphism.
- $\text{pt}$: Spec $k$.
- $C$: a connected smooth projective curve over $k$.
- $\text{Sym} C, C^{(n)}$: the scheme of effective divisors on (=symmetric powers of) $C$, and the component of divisors of degree $n$.
- $\check{C}^{n}, \check{C}^{(n)}$: the open subsets of distinct $n$-tuples of points, resp. multiplicity free divisors of degree $n$, on the curve.
for schemes living over any partially symmetrized powers of the curve, the restriction of their Cartesian product over the multiplicity-free locus.

$\kappa = \kappa(C)$ the field of rational functions on $C$.

$|C| = C(k)$ the set of closed points of $C$.

$v$ for $v \in |C|$, it denotes the completion of the local ring at $v$.

$F_v$ the fraction field of $\mathfrak{o}_v$. By choosing a local coordinate $t$ we have a non-canonical isomorphism $\mathfrak{o}_v \cong k[t] =: \mathfrak{o}$ and $F_v \cong k((t)) =: F$. We sometimes implicitly make this identification when the choice of local coordinate is irrelevant.

$\mathbb{N}$ the monoid of non-negative integers.

$G$ a connected reductive group over $k$.

$T$ the (abstract) Cartan of $G$, i.e., the reductive quotient of any Borel subgroup. We sometimes fix a splitting $T \hookrightarrow B \hookrightarrow G$ of the abstract Cartan into a Borel subgroup.

$W$ the (abstract) Weyl group of $G$.

$\Lambda_G$ the coweight (resp. weight) lattice of $T$. The index $G$ will often be omitted.

$\Lambda^+_G$ The monoid of dominant coweights (resp., dominant weights, antidominant coweights).

$\Lambda^{\text{pos}}_G$ The monoid generated by the non-negative integral span of the positive coroots (resp. roots) in $\Lambda_G$.

$\Delta_G$ the set of simple coroots (resp., roots) of $G$.

$2\rho_G \in \Lambda_G$ the sum of the positive coroots (roots) of $G$.

$\lambda \geq \mu$ For $\lambda, \mu \in \Lambda_G$, this means that $\lambda - \mu \in \Lambda^{\text{pos}}_G$.

$\hat{G}$ the Langlands dual group of $G$ over $\mathbb{Q}_\ell$, i.e., $\hat{G}$ is the connected reductive group where the weights, roots of $\hat{G}$ equal the coweights, coroots of $G$, etc.

$V^\lambda$ for $\lambda \in \Lambda_G$ either dominant or antidominant, this denotes the irreducible $\hat{G}$-module over $\mathbb{Q}_\ell$ with highest (resp. lowest) weight $\lambda$. Similarly, $V^\lambda$ denotes the irreducible $G$-module over $k$ for $\lambda \in \Lambda^+_G$.

variety will mean a reduced, finite type $k$-scheme (we will emphasize when a variety is irreducible).

$Z/H$ for a stack $Z$ with an action of an algebraic group $H$, this will denote the quotient stack.

$Z//H$ for an affine variety $Z$ over $k$, and a group $H$ acting on it, the invariant-theoretic quotient $\text{Spec} k[Z]^H$.

$X \times^G Y$ if $X, Y$ are stacks with $G$-actions, we will use this to denote the stack quotient $(X \times Y)/G$ by the diagonal action.

$L^+X, LX$ the formal arc and loop spaces of a scheme $X$ (see §2.2).

$D^b_c(Z)$ for an algebraic stack $Z$, this is the derived category of bounded constructible $\mathbb{Q}_\ell$-complexes on $Z$.

'sheaf' means a complex of sheaves. All functors between sheaves are derived functors.

$P(Z) \subset D^b_c(Z)$ when $Z$ is locally of finite type over $k$, this is the abelian category of perverse sheaves.
$pD^{\leq 0}$, $pD^{\geq 0}$, the subcategories and the cohomology functor with respect to the perverse $pH^0$-structure.

IC$_\mathbb{Z}$ the direct sum of the intersection cohomology complexes of all irreducible components of $\mathbb{Z}$ (if $k$ were a finite field then the IC sheaves should be normalized so they are pure of weight 0).

$X$ an affine $G$-spherical variety over $k$. (See §2.1 for notions pertaining to spherical varieties.)

$X^o$ the open $B$-orbit, for a fixed choice of Borel subgroup $B$.

$x_0 \in X^o(k)$ a fixed base point.

$H$ the stabilizer of $x_0$.

$X^\bullet$ the open $G$-orbit $H\backslash G$.

$X^{\text{can}}$ the “canonical” affine embedding $\text{Spec} \ k[X^\bullet]$ of $X^\bullet$.

$T_X$ the (abstract) Cartan of $X$, that is, the quotient by which the abstract Cartan of $G$ acts on $X^o/N$, where $N$ is the unipotent radical of $B$.

$\Lambda_X, \Lambda_X^\vee$ the character and cocharacter groups of $T_X$. Our assumptions on $X$ will identify $\Lambda_X$ with $\Lambda_G$, so it will often just be denoted by $\Lambda$.

$\tilde{G}_X$ the dual group of $X$; it has a canonical maximal torus isomorphic to the dual of $T_X$.

$\mathcal{V}$ the cone of invariant valuations of $X$; equivalently, the anticonormal chamber of the dual group of $X$.

$c_X^\vee \subset \Lambda_X$ the monoid of weights of $T_X$ on $k[X/N]$ (resp., its dual monoid).

$C_0 = C_0(X) \subset t_X$ the cone spanned by $c_X$, inside of the vector space spanned by $\Lambda_X$.

$C_X$ the intersection of $c_X$ with the cone $\mathcal{V}$ of invariant valuations.

$D(X)$ the set of irreducible $B$-stable divisors in $X$.

$D$ the set of colors, i.e., irreducible $B$-stable divisors which are not $G$-stable; equivalently, this can be identified with $D(X^\bullet)$.

$D(\alpha)$ for a simple root $\alpha$, the set of colors $D$ of $X^\bullet$ such that $DP_{\alpha} = X^\bullet$, where $P_{\alpha}$ is the parabolic generated by $B$ and the root space $\mathfrak{g}_{-\alpha}$.

$\varrho_X(D) = \tilde{\nu}_D$ for $D \in D(X)$, the associated $B$-invariant valuation, restricted to the group of nonzero $B$-eigenfunctions: $\tilde{\nu}_D : k(X)^{(B)} \to \mathbb{Z}$, and understood as a functional on the character group $\Lambda_X = k(X)^{(B)}/k^\times$.

$\mathfrak{c}_X$ the monoid generated by the $\tilde{\nu}_D$, $D \in D$.

$c_X^\mathfrak{p} \subset \Lambda_X$ the monoid generated by the $\tilde{\nu}_D$, $D \in D$.

$\mathfrak{p} \preceq \mathfrak{p}$ for $\lambda, \mu \in \Lambda_X$, this means that $\mu - \lambda \in c_X^\mathfrak{p}$.

$D_{\text{sat}}^G(X)$ the set of those primitive (=indecomposable) elements in $c_X^\mathfrak{p}$ that are minimal for in the $\preceq$ partial order.

$\text{Bun}_G, \text{Bun}_B$ the moduli stack of $G$-bundles, resp. $B$-bundles, on $C$.

$\mathcal{M}_X$ the “global model” of generic maps from a curve to $X/G$; it lives over $\text{Bun}_G$. The restriction of such a map, defined over $k$, to the formal neighborhood of a point $v \in |C|$ gives rise to a well-defined “valuation”, that is, an element of $(X^\bullet(F_v) \cap X(\mathfrak{o}_v))/G(\mathfrak{o}_v)$.

See Section 3 for the various models of the arc space. For any model, when $X$ is understood, the index will be omitted.
the “Zastava model” of generic maps from a curve to \( X/B \); it lives over Bun\(_B\). The restriction of such a map, defined over \( k \), to the formal neighborhood of a point \( v \in |C| \) gives rise to a well-defined element of \((X^\circ(F_v) \cap X(\sigma_v))/B(\sigma_v)\) Drinfeld’s compactification of Bun\(_B\), see §4.1.

\( \overline{\text{Bun}_B} \) the compactified Zastava model (Section 4).

\( \mathcal{Y}_X \) \( \mathcal{Y}_X \) the natural maps \( \pi : \mathcal{Y}_X \to \mathcal{A} \), \( \bar{\pi} : \mathcal{Y}_X \to \mathcal{A} \) (extending \( \pi \)).

\( \mathcal{A} \) the global/Zastava model for the \( TX \)-space \( X/N \).

\( \mathcal{X}_\mathcal{C} \) the “semisimple” \( L^+X \).

\( X^\bullet(F)_{\mathcal{C}, \mathcal{Y}_X} \) the \( G(\mathcal{c}) \)-orbit on \( X(F) \) parametrized by \( \mathcal{C} \in V \cap \mathcal{T}_\mathcal{C} \) (Theorem 2.2.5), and the corresponding stratum of the loop space. When \( \mathcal{C} \in \mathcal{T}_\mathcal{C} \), these belong to \( X(\sigma) \), resp. the arc space \( L^+X \).

\( \mathcal{M}^\Theta \) for \( \mathcal{M} \in \mathcal{M}^\Theta \), the stratum of \( \mathcal{M} \) containing those maps whose multiset of nontrivial valuations (as elements of \( \mathcal{T}_\mathcal{C} \)) is equal to \( \Theta \).

\( \mathcal{A}^\mathcal{C} \) the connected component of \( \mathcal{A} \) of maps with total valuation \( \lambda \in \mathcal{T}_\mathcal{C} = X(F)/T(\sigma) \).

\( \mathcal{Y}_\mathcal{C}^\lambda, \mathcal{Y}_\mathcal{C}^\lambda \) the preimage of \( \mathcal{A}^\mathcal{C} \) in \( \mathcal{Y}_\mathcal{C} \), resp. in \( \overline{\mathcal{Y}_\mathcal{C}} \). They live over strata \( \overline{\text{Bun}_B^\lambda} \), \( \text{Bun}_B^\lambda \) of Bun\(_B\), resp. \( \overline{\text{Bun}_B} \).

\( \mathcal{Y}_\mathcal{C}^\mathcal{C}, \mathcal{Y}_\mathcal{C}^\mathcal{C} \) the fiber products of \( \mathcal{Y}_\mathcal{C}^\mathcal{C} \), \( \mathcal{Y}_\mathcal{C}^\mathcal{C} \) with \( \mathcal{M}^\Theta \) over \( \mathcal{M} \).

\( \mathcal{Y}_\mathcal{C}^D \) for \( D \in \mathbb{N}^P \), a certain connected/irreducible component of the “open Zastava” space \( \mathcal{Y}_\mathcal{C}^\mathcal{C} = \mathcal{Y}_\mathcal{C}^\mathcal{C} \), defined in §5.4. The question mark ? corresponds to the valuation \( gx(D) \).

\( \overline{\mathcal{M}}^\Theta \) the closure of the stratum \( \mathcal{M}^\Theta \). Note that \( \mathcal{Y}_\mathcal{C}^\mathcal{C} \), \( \mathcal{Y}_\mathcal{C}^\mathcal{C} \), in contrast, are not closures of strata, but strata of the compactified Zastava space. In the case of the global model, there is no room for confusion, so we allow ourselves this notation, for typographical reasons.

\( \mathcal{C}_\nu \) the partially symmetrized power \( C^\mathcal{C} \) when \( \nu \) is thought of as a multiset \( \mathcal{C} \) in the simple coroots, a stratum of \( \text{Bun}_B^\mathcal{C} \), and a stratum of \( \overline{\mathcal{Y}_\mathcal{C}^\mathcal{C}}, \) isomorphic, respectively, to \( \mathcal{C}_\nu \times \text{Bun}_B^\mathcal{C} \rightarrow \text{Bun}_B \) and \( \mathcal{C}_\nu \times \overline{\mathcal{Y}_\mathcal{C}^\mathcal{C}} \) (see §4.2).

\( \text{Gr}_G, \text{Gr}_B \) the affine Grassmannian of \( G \), resp. \( B \).

\( \text{Gr}_G, \text{Sym}_C, \text{Gr}_B, \text{Sym}_C \) the Beilinson–Drinfeld affine Grassmannians, living over \( \text{Sym}_C \) (see §3.7).

\( \text{Gr}_G^\mathcal{C}, \overline{\text{Gr}_G^\mathcal{C}} \) for \( \mathcal{C} \in \mathcal{M}_G \), the \( L^+G \)-orbit in the affine Grassmannian containing the class of \( \mathcal{C} \), and its closure.

\( \overline{\text{Gr}_G^\mathcal{C}, \overline{\text{Gr}_G^\mathcal{C}}} \) for \( \mathcal{C} \in \mathcal{M}_G \), the multi-point version of \( \overline{\text{Gr}_G^\mathcal{C}} \), see §5.2.1.

\( \mathcal{S}_\mathcal{C}, \overline{\mathcal{S}_\mathcal{C}} \) the “semi-infinite” LN-orbit of \( t^\Theta \) in \( \text{Gr}_G \), and its closure.
\[ \mathcal{Y}^\lambda, \mathcal{Y}^\check{\lambda} \] the central fibers of \( \mathcal{Y}^\lambda, \mathcal{Y}^\check{\lambda} \), living over a point of the diagonal stratum \( C \hookrightarrow A^\lambda \). They can be identified as subspaces of \( S^\lambda, S^\check{\lambda} \) (see §4.3).

\[ \mathcal{B}_{X, \lambda} \] for \( \lambda \in \mathfrak{c}_X \), the set of all irreducible components of critical dimension of the central fiber \( \mathcal{Y}^\lambda \), see Proposition 6.5.1.

\[ \mathcal{B}^+, \mathcal{B}_X \] the union of all \( \mathcal{B}_{X, \lambda}, \lambda \in \mathfrak{c}_X \), and the “crystal of \( X \)” (§7.1.4).

2. Spherical varieties and their arc spaces

2.1. Spherical varieties. Let \( X \) be an affine \( G \)-spherical variety over \( k \). Let \( X^o \) denote the open \( B \)-orbit. We choose and fix a point \( x_0 \in X^o(k) \) and let \( H \) denote its stabilizer. Let \( X^* = H \backslash G \) denote the open \( G \)-orbit.

The quotient \( X^o \backslash /N \) has an action of the universal Cartan \( T = B/N \), and is a torsor for a quotient torus \( T \to T_X \). By our choice of base point, we can identify this torsor with \( T_X \). In the rest of this paper, we will assume that our spherical variety satisfies \( T_X = T \); however, for now we proceed with general definitions.

All important combinatorial invariants of the spherical variety live in the rational vector space \( t_X \) spanned by the character group \( \Lambda_X \) of this torus, or on the dual vector space \( \check{t}_X \), containing the dual lattice \( \check{\Lambda}_X \). By “lattice points”, below, we will mean points belonging to one of these lattices. The spaces \( t_X, \check{t}_X \) are the root and coroot space for the dual group \( \check{G}_X \) of \( X \) live.\(^9\) The antidominant Weyl chamber for \( \check{\Lambda}_X \) is denoted by \( \check{V} \) in the theory of spherical varieties, because it coincides with the so-called cone of \( G \)-invariant valuations, see [Kno91]. Up to this point, all data depend only on the open \( G \)-orbit \( X^* \), not on its affine embedding \( X \).

The affine embedding \( X \) defines an affine toric embedding \( X/\!\!/N \) of \( T_X \), described by the cone \( C_0(X) \subset t_X \) whose lattice points are all cocharacters \( \check{\lambda} \) into \( T_X \) such that \( \lim_{t \to 0} \check{\lambda}(t) \in X/\!\!/N \). We will denote by \( \mathfrak{c}_X \) the monoid of lattice points \( \check{\Lambda}_X \cap C_0(X) \subset t_X \), and by \( \mathfrak{c}_X \) its intersection with the cone \( \check{V} \) of invariant valuations. The cone \( C_0(X) \subset t_X \) has a canonical set of generators \( \check{\nu}_D \), the valuations associated to all \( B \)-stable divisors \( D \subset X \). The set of all irreducible \( B \)-stable divisors in \( X \) will be denoted by \( \mathcal{D}(X) \), and by “valuation associated” we mean the restriction of the corresponding valuation to the group of nonzero \( B \)-eigenfunctions: \( \check{\nu}_D : k(X)^{B} \to \mathbb{Z} \), which factors through the character group \( \Lambda_X \) and hence can be identified with an element of \( \check{\Lambda}_X \subset t_X \). The map \( \mathcal{D}(X) \ni D \to \check{\nu}_D \in \check{\Lambda}_X \) will be denoted by \( \check{\rho}_X \). Inside of \( \mathcal{D}(X) \) there is a distinguished subset \( \mathcal{D} \), depending only on the open \( G \)-orbit \( X^* \), which consists of the closures of \( B \)-stable divisors in \( X^* \); those are called colors.

---

\(^9\)The Gaitsgory–Nadler dual group was defined in a Tannakian way in [GN10], but not completely identified in all cases. A combinatorial description of a dual group (presumably the same) was subsequently afforded by Knop and Schalke [KS17]. The invariants that we present here are those of Knop and Schalke, which match standard invariants of the theory of spherical varieties. For this paper, however, this distinction between constructions of the dual group is immaterial, as we impose the condition that “all spherical roots are of type \( T \)”, which implies that in both versions of the dual group, \( \check{G}_X = \check{G} \).
We remark that the "valuation" map $\varrho_X$ may fail to be injective, but this can only happen when two colors have the same image. If this is a case for $X^* = H \setminus G$, there is always a torus covering of it such that all colors have distinct valuations (see §5.3); for example, $GL_1 \setminus PGL_2$ has two colors with valuation $\frac{1}{2}$, but their preimages in $GL_1 \setminus GL_2$ (where $GL_1$ is embedded as the general linear group of a one-dimensional subspace) induce different valuations. In any case, colors give rise to a map $N^D \to c_X$, whose image we denote by $c^D_X$. We will often abuse language and write "colors" for the images of the basis elements in $c^D_X$.

We define an ordering $\preceq$ on $\tilde{\Lambda}_X$ by postulating that $\tilde{\lambda} \preceq \tilde{\lambda}'$ if $\tilde{\lambda}' - \tilde{\lambda}$ can be written as a non-negative integral combination of the valuations $\tilde{\nu}_D$, with $D \in \mathcal{D}$, i.e., if $\tilde{\lambda}' - \tilde{\lambda} \in c^D_X$. We use the symbol $\preceq$ for the ordering on $\tilde{\Lambda}_G$ defined by the positive coroots of $G$, that is, $\tilde{\lambda} \preceq \tilde{\lambda}'$ iff $\tilde{\lambda}' - \tilde{\lambda}$ is a sum of positive coroots. Notice that the ordering $\preceq$ is not defined simply in terms of the cone spanned by the $\tilde{\nu}_D$’s: there can be non-comparable lattice points in this cone. As we will see later, this ordering describes the closure relations on the global model of the arc space of $X$.

### 2.1.1. Spherical roots of type $T$

From Section 3 onwards we assume that $T_X = T$, equivalently, $B$ acts simply transitively on $X^\circ$. From Section 5 on we assume, further, that all spherical roots are of type $T$. Let us explain what this means: For a simple root $\alpha$ of $G$, let $P_\alpha \supset B$ denote the corresponding parabolic of semisimple rank one. The quotient $P_\alpha \setminus \mathfrak{R}(P_\alpha)$ by its radical is isomorphic to $PGL_2$, and the invariant-theoretic (or geometric) quotient $X^\circ P_\alpha \setminus \mathfrak{R}(P_\alpha)$ is a spherical variety for $PGL_2$. In characteristic zero, over an algebraically closed field, those belong to one of the following types, see [Kno95, Lemma 3.2]:

- a point: $PGL_2 \setminus PGL_2$;
- type $T$: $\mathbb{G}_m \setminus PGL_2$;
- type $N$: $\mathcal{N}(\mathbb{G}_m) \setminus PGL_2$, where $\mathcal{N}$ denotes normalizer;
- type $U$: $N \setminus PGL_2$, where $N \subset S \subset B$.

In positive characteristic there are some more cases, investigated by Knop in [Kno14]. Over a field $\mathbb{F}$ that is not algebraically closed (but with $G$ split), the multiplicative group $\mathbb{G}_m$ of type $T$ can be an arbitrary one-dimensional torus.

Our assumption from Section 5 onwards is that for every simple root $\alpha$, this $PGL_2$-spherical variety is isomorphic to $T_\alpha \setminus PGL_2$ over the algebraic closure, where $T_\alpha$ is a torus. Since we are assuming here that $\mathbb{F}$ is either finite or algebraically closed, in the finite field case this torus is either split, or splits over the unique quadratic extension. Our assumptions imply that the stabilizer in $P_\alpha$ of a point on the open orbit is isomorphic to $T_\alpha$, and that there are precisely two colors $D^+_\alpha, D^-_\alpha$ contained in $X^\circ P_\alpha$ (the $\pm$ labelling is arbitrary), which are fixed by the Galois group, if $T_\alpha$ is split, or interchanged by the action of the Frobenius element, if it is non-split. We will denote the set of these two elements by $\mathcal{D}(\alpha) \subset \mathcal{D}$; notice that these sets are not disjoint as $\alpha$ varies. Moreover, the associated valuations satisfy (see [Lum97, §3.4]):

$$\tilde{\nu}_{D^+_\alpha} = -s_\alpha \tilde{\nu}_{D^-_\alpha},$$

$$\tilde{\nu}_{D^+_\alpha} + \tilde{\nu}_{D^-_\alpha} = \tilde{\alpha},$$

and finally an element $D \in \mathcal{D}$ belongs to $\mathcal{D}(\alpha)$ iff $\langle \alpha, \tilde{\nu}_D \rangle > 0$ (in which case $\langle \alpha, \tilde{\nu}_D \rangle = 1$, by the above). The map $D \mapsto \tilde{\nu}_D$ is obviously Galois-equivariant, which means (since $G$ is assumed split) that in the non-split case we have $\tilde{\nu}_{D^+_\alpha} = \tilde{\nu}_{D^-_\alpha} = \frac{\alpha}{2}$.

**Remark 2.1.2.** A very straightforward way to compute the valuations $\tilde{\nu}_{D^\pm}$ in any example is the following: If all roots are of type $T$ and $T_X = T$, the stabilizer $S$ of a point in the open $P_\alpha$-orbit on $X$ is a subgroup isomorphic (over the algebraic closure) to $\mathbb{G}_m$. Choose a Borel
subsection B containing $S$. An isomorphism $\mathbb{G}_m \simeq S$ gives rise to a cocharacter $\mathbb{G}_m \to B \to T$. There are two such isomorphisms, and they correspond to the valuations $\nu_{D, \ell}$.

2.1.3. Assumptions in positive characteristic. Throughout this paper, we use some results on the structure of spherical varieties that have been proven in characteristic zero. By standard arguments, such results hold for any integral model of the spherical variety after inverting a sufficiently large set of primes. However, they are not always true unconditionally in positive characteristic. Hence, for our arguments to work, we need the following facts about our affine spherical variety $X$ to hold:

(i) The local structure theorem of [BLV86, Théorème 3.5] holds for a smooth, toroidal completion $\overline{X}$ of $X$. This ensures that the results of §2.2 hold. (Notice that the Luna–Vust theory of spherical embeddings holds in arbitrary characteristic over an algebraically closed field by [Kno91]; we point the reader there for a definition of toroidal embeddings.)

(ii) In §8, assume that $k[X]$ admits a $G$-module filtration with subquotients isomorphic to dual Weyl modules of $G$.

2.2. The formal loop space. For any $k$-scheme $X$, define the space of formal arcs by

$$L^+ X(R) = X(R[[t]])$$

for a test ring $R$. It is well-known (cf. [KV04, Proposition 1.2.1]) that $L^+ X$ is representable by a scheme (of infinite type), which is the projective limit of the schemes $L^+_n X$, $n \in \mathbb{N}$, representing the spaces of $n$-arcs $L^+_n X(R) = X(R[t]/t^n)$. If $X$ is of finite type over $k$, then so is each $L^+_n X$. If $X$ is smooth over $k$, then each $L^+_n X$ is smooth over $k$ and $L^+ X$ is formally smooth over $k$. If $X$ is affine, then so are $L^+_n X$ and $L^+ X$.

Define the formal loop space $LX(R) = X(R[[t]])$. If $X$ is affine, then $LX$ is representable by an ind-affine ind-scheme, and we have a closed embedding $L^+ X \hookrightarrow LX$.

2.2.1. Let $X$ be an affine spherical $G$-variety. Recall that we have an open $G$-stable subscheme $X^\bullet \subset X$. Define

$$L^\bullet X := LX - L(X - X^\bullet),$$

which admits an open embedding into $LX$. The $G$-action on $X$ induces a natural action of $L^+ G$ on $LX$ and $L^+ X$, $L^\bullet X$ are stable under this action.

Remark 2.2.2. The $k$-points of $L^\bullet X$ are in bijection with $X^\bullet(k((t)))$. Since $X^\bullet$ is in general not affine, however, $X^\bullet(k((t)))$ does not always have an ind-scheme structure. Even when $X^\bullet$ is affine, $L(X^\bullet)$ may not be isomorphic to $L^\bullet X$.

Example 2.2.3. Let $X = \mathbb{A}^1$ with the scaling $\mathbb{G}_m$-action. Then $L^+ X = \mathbb{A}^\infty$, where we consider $\mathbb{A}^\infty = \text{Spec } k[a_0, a_1, \ldots]$ as the coefficients of infinite Taylor series, and the ind-scheme $LX = \lim_{\to} \text{Spec } k[a_{-m}, a_{-m+1}, \ldots]$ considered as the coefficients of Laurent series. Let $X^\bullet = \mathbb{A}^1 - \{0\}$. Then $L^\bullet X = LX - \{0\}$ so $L^+ X \cap L^\bullet X = \mathbb{A}^\infty - \{0\}$, whereas $L^+ (X^\bullet) = \mathbb{G}_m \times \mathbb{A}^\infty$.

2.2.4. Orbits on the formal loop space. For ease of notation, let $\mathfrak{o} = k[t]$ and $F = k((t))$, so $L^+ G(k) = G(\mathfrak{o})$, $L^\bullet X(k) = X^\bullet(F)$. We review the decomposition of $G(\mathfrak{o})$-orbits on $X^\bullet(F)$ due to [LV83]. We present the reformulation of this result found in [GN10, Theorem 3.3.1].

Let $X^\bullet(F)/G(\mathfrak{o})$ denote the set of equivalence classes of $G(\mathfrak{o})$-orbits in $X^\bullet(F)$. For a cocharacter $\hat{\theta} \in \hat{\Lambda}_G$ we let $\hat{\theta} \in G(F)$ denote the image of the uniformizer $t \in \mathfrak{o}$ under the map $\hat{\theta} : \mathbb{G}_m \to T \subset G$.

Theorem 2.2.5 ([LV83], [GN10, Theorem 3.3.1]). Let $X$ be an affine spherical variety.
(i) There is a bijection of sets $V \cap \tilde{\Delta}_X \cong X^\bullet(F)/G(o)$.
(ii) This bijection restricts to a bijection $\tilde{c}_X \cong (X(o) \cap X^\bullet(F))/G(o)$.

The theorem can be viewed as a generalization of the Cartan decomposition. We have an embedding $T_X \hookrightarrow X^\circ : a \mapsto x_0 \cdot a$, depending on a (fixed) choice of $x_0 \in X^\circ(k)$. The bijection in (i) can be described explicitly by

$$\tilde{\theta} \mapsto X^\bullet(F)_{G,\tilde{\theta}} := x_0 \cdot t^{\tilde{\theta}} G(o)$$

for $\tilde{\theta} \in \nu \cap \tilde{\Delta}_X$, where $x_0$ is considered as an element of $X^\bullet(o)$.

Below we review the well-known fact that $L^\bullet X$ is stratified by $L^+G$-orbits $L^\theta X$, where $L^\theta X$ is a locally closed scheme whose set of $k$-points identifies with $X^\bullet(F)_{G,\theta}$.

**Proposition 2.2.6.** Let $\tilde{\theta} \in \nu \cap \tilde{\Delta}_X$. Then $L^\theta X$ is a formally smooth $k$-scheme, and $L^\theta X$ is open in its closure in $LX$. Therefore the collection of $L^\theta X, \tilde{\theta} \in \nu \cap \tilde{\Delta}_X$, form a stratification of $L^\bullet X$, in the sense that the strata are disjoint and contain all the $k$-points.

**Proof.** Since $k[X]$ is a finitely generated $k$-algebra and locally finite as a $G$-module, there exists a $G$-module $V$ and a closed $G$-equivariant embedding $X \hookrightarrow V$. This induces an ind-closed embedding $LX \hookrightarrow LV$, where $LV = V((t)) = \lim_{\to \nu} t^{-n} V[t]$ is a Tate vector space. After scaling by $t^n$, we may assume that $x_0 \cdot \tilde{\theta} \in LX$ maps to $L^+V = V[t]$. Then $x_0 \cdot t^{\tilde{\theta}} \in V(k[t])$ defines a point in $V(k[t]/t^n) = L^+_n V(k)$ for every $n \in \mathbb{N}$. The smooth affine group $L^+_n G$ acts on $L^+_n V$, so by the usual theory of affine algebraic groups, the orbit of $x_0 \cdot t^{\tilde{\theta}}$ is smooth. Denote this orbit by $L^\theta_n X$. Let $L^\theta_n X$ denote its (reduced) closure in $L^+_nX$. Then $L^\theta_n X \hookrightarrow L^\theta_{n+1} X$ is an open embedding, and $L^\theta_n X$ is affine. The kernel $L^+_{n+1} G \to L^+_n G$ is a unipotent group, so the map of orbits $L^\theta_{n+1} X \to L^\theta_n X$ is affine. Therefore we can take projective limits to get an open embedding of schemes

$$L^\theta X = \varprojlim L^\theta_n X \hookrightarrow \varprojlim L^\theta_n X = L^\theta X,$$

where the equalities are essentially by definition. □

**Remark 2.2.7.** Observe that if $\tilde{\theta} \in \tilde{c}_X$, then in particular $\tilde{\theta} \in L^\bullet_G X$ is antidominant. Therefore $w \tilde{\theta} - \tilde{\theta} \in L^\bullet_G X \subset \tilde{c}_X$ for any $w \in W_X$, and hence $w \tilde{\theta} \in \tilde{c}_X$. We suggest that the monoid $\tilde{c}_X = C_0(X) \cap \nu \cap \tilde{\Delta}_X$ should be thought of as the set of $W_X$-orbits in $\tilde{\Delta}_X$ that are entirely contained in the cone $C_0(X)$.

### 2.3. Satellites of $H$

In this subsection we will use properties of toroidal compactifications of $X$. We refer the reader to [SV17, §2.3-2.5], [Kno91], [GN10, §8] for an overview.

Let $\overline{X}$ denote a complete, smooth toroidal embedding of $X^\bullet = H \backslash G$ (the embedding is not simple if $N_G(H)/H$ is not finite). For any $\tilde{\theta} \in \nu \cap \tilde{\Delta}_X$, the point $x_0 \cdot t^{\tilde{\theta}} \in X^\bullet(F) \subset \overline{X}(F)$ defines an $o$-point of $\overline{X}$ by the valuative criterion of properness. In particular, we can take the limit as $t \to 0$ to get a point $x_{\tilde{\theta}} \in \overline{X}(k)$. Let $Z \subset \overline{X}$ denote the $G$-orbit of $x_{\tilde{\theta}} := \lim_{t \to 0} x_0 \cdot t^{\tilde{\theta}} \in \overline{X}(k)$. Let $H_{\tilde{\theta}}$ denote the stabilizer of $G$ acting on $x_{\tilde{\theta}}$, so $Z \equiv H_{\tilde{\theta}} \backslash G$.

Let $J \subset \Delta_X$ denote the set of spherical roots $\gamma$ such that $\langle \gamma, \tilde{\theta} \rangle = 0$. In the language of [SV17, §2.3.6], the orbit $Z$ “belongs to $J$-infinity”. Let $X^\bullet_J = H_J \backslash G$ denote the open $G$-orbit on the normal bundle $N_Z \overline{X}$ of $Z$ in $\overline{X}$; this is called a boundary degeneration of $X$. As the notation suggests, $X^\bullet_J$ and $H_J$ depend only on the subset $J$ and not $\tilde{\theta}$ (see [SV17, Proposition 2.5.3]). *Loc. cit.* also gives a canonical identification of the open $B$-orbits $X^\circ \cong X^\bullet_J$. 
The relation between $\tilde{H}_\theta$ and $H_J$ is as follows: Let $D^G_J(X)$ denote the set of $G$-stable divisors in $\overline{X}$ which contain $Z$. Then $\tilde{H}_\theta$ is a semidirect product of $\mathbb{G}^{D^G_J(X)}_{m!}$ and $H_J$. In particular, $\tilde{H}_\theta$ is connected if and only if $H_J$ is connected.

**Lemma 2.3.1.** Assume that $B$ acts simply transitively on $X^\circ$. Then the satellite subgroup $H_J \subset G$ is connected for any subset $J \subset \Delta_X$.

**Proof.** We have $X^\circ \cong X^\circ_J \cong B$. Let $H^0_J$ denote the connected component of $H_J$ containing identity. Then $H^0_J \setminus G \to H_J \setminus G$ is a finite covering sending the open $B$-orbit of $H^0_J \setminus G$ to $X^\circ_J$. Since $B$ acts on $X^\circ_J \cong X^\circ$ with trivial stabilizer, the covering must be an isomorphism. \hfill \Box

**Corollary 2.3.2.** Assume that $X^\circ \cong B$. Let $\tilde{\theta} \in \mathcal{V} \cap \tilde{A}_X$. Then the stabilizer of the group ind-scheme $LH$ acting on $t^\theta \in Gr_G$ is a connected scheme.

**Proof.** We consider $x_0 \cdot t^\theta$ as a point in $L^+X(k) = \overline{X}(k)$. Observe that $\text{Stab}_{LH}(t^\theta, Gr_G) = LH \cap t^\theta(L^+G)\cdot t^{-\theta}$ conjugates to $t^{-\theta}(LH)\cdot t^\theta \cap L^+G = \text{Stab}_{L^+G}(x_0 \cdot t^\theta, L^+\overline{X})$. Since $L^+\overline{X}$ is the projective limit of $L^+_n\overline{X}$, the stabilizer $\text{Stab}_{L^+G}(x_0 \cdot t^\theta, L^+\overline{X})$ is a pro-unipotent extension of $\text{Stab}_G(x_0, \overline{X}) = \tilde{H}_\theta$. Lemma 2.3.1 (and the comment preceding it) imply that $\tilde{H}_\theta$ is connected, so we deduce that $\text{Stab}_{LH}(t^\theta, Gr_G)$ is also connected. \hfill \Box

### 3. Models for the arc space

In this section we define two models (in the sense of Grinberg–Kazhdan) for the arc space of $X$, both of which were already introduced in [GN10] and go back to ideas of Drinfeld. We call these the global and Zastava models (the term ‘global’ refers to the fact that the model depends on the curve $C$). The global model $\mathcal{M}_X$ is crucial because it allows us to model the $G(\mathfrak{o})$-orbits of $X(\mathfrak{o})$, something which cannot be done directly via the Zastava model. On the other hand, the Zastava model $\mathfrak{Y}_X$ is more suitable for finite type calculations.

Various incarnations of these constructions have been used in [FM99, FFKM99, BG02, BFGM02, BFG06, ABB+05]. To place our work in this context, we remark that when $X = \overline{N\setminus G}^{\text{aff}}$ we have $\mathcal{M}_X = \overline{\text{Bun}_N}$ is Drinfeld’s compactification of $\text{Bun}_N$ and $\mathfrak{Y}_X$ is “the” Zastava space of [FM99] (in this case $\tilde{G}_X = \tilde{T}$).

While Gaitsgory–Nadler define the global and Zastava models for any affine $X$, in order to avoid various technical difficulties they faced (such as the existence of twisted strata, which are related to the existence of disconnected stabilizer subgroups) we make the following simplifying assumption:

Starting from §3.3, we assume for the rest of the paper that $B$ acts simply transitively on $X^\circ$. If $\tilde{G}_X = \tilde{G}$ and $X$ has no spherical roots of type $N$, then the above assumption always holds.

**Remark 3.0.1.** The assumption that $B$ acts simply transitively on $X^\circ$ implies that $H$ must be connected, by Lemma 2.3.1.

### 3.1. Global model

Gaitsgory–Nadler [GN10] define certain stacks of meromorphic quasimaps from $C \to X/G$ to model $X^\bullet(F)$, the loop space of $X^\bullet$. Our global model $\mathcal{M}_X$ is the substack consisting of those quasimaps that extend to regular maps$^{10}$ $C \to X/G$.

---

$^{10}$In the literature, when $X = \overline{N\setminus G}$ regular maps $C \to \overline{N\setminus G}$ are still referred to as quasimaps to $N\setminus G$. 
3.1.1. **Definition.** Define the stack
\[ M_X := \text{Maps}_\text{gen}(C, X/G) \cap X^\bullet/G \]

to be the open substack of \( \text{Maps}(C, X/G) \) representing maps generically landing in \( X^\bullet/G = (H\backslash G)/G = H\backslash pt \).

An \( S \)-point of \( M_X \) is a map \( f : C \times S \to X/G \), which is equivalent to the datum \((\mathcal{P}_G, \sigma)\) where

- \( \mathcal{P}_G \) is a \( G \)-bundle on \( C \times S \) and
- \( \sigma : C \times S \to X \times G \mathcal{P}_G \) is a section over \( C \times S \) such that
- \( \sigma|_{\text{Spec} \, k(C) \times S} \) lands in \( X^\bullet \times G \mathcal{P}_G = H\backslash \mathcal{P}_G \) and gives \( \mathcal{P}_G|_{\text{Spec} \, k(C) \times S} \) the structure of an \( H \)-bundle.

We call the preimage \( \sigma^{-1}(X^\bullet \times G \mathcal{P}_G) \subset C \times S \) the locus of \( G \)-nondegenerate points.

**Proposition 3.1.2.** The natural map \( M_X \to \text{Bun}_G \) is schematic locally of finite type. In particular, \( M_X \) is an algebraic stack locally of finite type over \( k \).

**Proof.** Since \( M_X \) is an open substack of \( \text{Maps}(C, X/B) \), it suffices to show the latter is schematic locally of finite type over \( \text{Bun}_G \). Let \( S \to \text{Bun}_G \) correspond to a \( G \)-bundle \( \mathcal{P}_G \) on \( C \times S \). Then the fiber product \( S \times_{\text{Bun}_G} \text{Maps}(C, X/G) \) is isomorphic to the space of sections \( C \times S \to X \times G \mathcal{P}_G \) over \( C \times S \). This space is representable by a \( k \)-scheme locally of finite type ([FGI+05, Theorem 5.23]). \( \square \)

If \( X = H \backslash G \) is homogeneous, then \( M_X = \text{Maps}(C, H\backslash pt) = \text{Bun}_H \).

3.1.3. **Adelic description.** For motivational purposes, we give an “adelic” description of the \( k \)-points of \( M_X \). Let \( \hat{A} \) denote the restricted product \( \prod_{v \in |C|} F_v \) and \( \emptyset = \prod_{v \in |C|} \emptyset_v \). (If \( k = \mathbb{F}_q \) then \( \hat{A} \) is the ring of adeles of the function field \( k = k(C) \).)

The underlying set of meromorphic quasimaps \( C \rightarrow X/G \) can be identified with the set
\[ X^\bullet(k)^{G(k)} \times G(\hat{A})/G(\emptyset) = H(k) \backslash G(\hat{A})/G(\emptyset). \]

Note that the \( G \)-action on \( X \) induces a map
\[ X^\bullet(k)^{G(k)} \times G(\hat{A})/G(\emptyset) \to X^\bullet(\hat{A})/G(\emptyset) \subset X(\hat{A})/G(\emptyset). \]

The underlying set of \( M_X(k) \) identifies with the preimage of \( (X^\bullet(\hat{A}) \cap X(\emptyset))/G(\emptyset) \) under the above map.

Note that the topologies on \( X^\bullet(\hat{A}) \) vs. \( X(\hat{A}) \) are different: the fact that the geometric constructions above depend on \( X \) can be expressed by saying that we are always using the topology of \( X(\hat{A}) \), not of \( X^\bullet(\hat{A}) \).

3.1.4. For any set \( S \), define the set of unordered **multisets** in \( S \) to be the formal direct sum
\[ \text{Sym}^\infty(S) := \bigoplus_{\lambda \in \mathbb{S}} \mathbb{N}[\hat{\lambda}]. \]

An element of \( \text{Sym}^\infty(S) \) is a formal sum \( \mathcal{P} = \sum_{\lambda \in S} N_{\lambda}[\hat{\lambda}] \) where \( N_{\lambda} \geq 0 \) are integers and only finitely many are nonzero. For a multiset \( \mathcal{P} \), define
\[ C^\mathcal{P} = \left( \prod_{\lambda \in S} C^{(N_{\lambda})} \right) \]

to be the open subscheme of \( C^\mathcal{P} := \prod C^{(N_{\lambda})} \) with all diagonals removed, i.e., the subscheme of multiplicity free divisors. We write \( \mathcal{P} = 0 \) for the zero element, and we will use the convention
\[ C^\Psi = C^\Psi = \text{pt}. \] If we define \( |\Psi| = \sum N_\lambda \), then there are natural maps \( C^{(|\Psi|} \to C^\Psi \to C^{(|\Psi|)} \subset \text{Sym} C \).

Now consider the case when \( S = M - 0 \) for a commutative monoid \( M \). Then \( \text{Sym}^\infty(M - 0) \) identifies with the set of partitions of an arbitrary element in \( M \). Given a partition \( \Psi \in \text{Sym}^\infty(M - 0) \) as above, we define \( \deg : \text{Sym}^\infty(M - 0) \to M \) by
\[ \deg(\Psi) := \sum_{\lambda \in M - 0} N_\lambda \bar{\lambda} \]
with addition taking place in \( M \). There is a natural order on the set \( \text{Sym}^\infty(M - 0) \): we say that \( \Psi \) refines \( \Psi' \) if the difference \( \Psi - \Psi' \) viewed as an element of \( \bigoplus_{\lambda \in M - 0} \mathbb{Z}[\bar{\lambda}] \) can be written as a sum of elements of the form \( [\lambda'] + [\lambda''] - [\bar{\lambda}] \) with \( \lambda' + \lambda'' = \bar{\lambda} \) in \( M \).

Let \( \text{Prim}(M) \) be the set of primitive elements of \( M \), i.e., the elements \( \bar{\lambda} \in M - 0 \) that cannot be decomposed as a sum \( \bar{\lambda} = \lambda_1 + \lambda_2 \) where \( \lambda_1, \lambda_2 \in M - 0 \). Then any partition in \( \text{Sym}^\infty(M - 0) \) can be refined to an element in \( \text{Sym}^\infty(\text{Prim}(M)) \).

3.1.5. Stratification of \( M_X \). We would like to stratify \( M_X \) according to \( G(\mathfrak{o}_v)\)-orbits of \( X(\mathfrak{o}_v) \cap X^*(F_v) \) at each \( v \in |C| \), described in Theorem 2.2.5.

Consider the set \( \text{Sym}^\infty(c_X - 0) \) of partitions in \( c_X \), as defined in §3.1.4. Let
\[ \hat{\Theta} = \sum_{\bar{\theta} \in c_X - \{0\}} N_{\bar{\theta}}[\bar{\theta}] \]

denote such a partition. We will write \( \hat{\Theta} = 0 \) for the empty partition and \( \hat{\Theta} = [\bar{\theta}] \) for the singleton partition corresponding to a single element \( \bar{\theta} \).

In §A.3, we define locally closed substacks \( M^{\hat{\Theta}}_\lambda \) of \( M_X \) ranging over all partitions \( \hat{\Theta} \) in \( c_X \). For simplicity we only describe \( M^{\hat{\Theta}}_\lambda \) on \( k \)-points below: Such a point consists of a map \( f : C \to X/G \) and a formal sum \( \sum_{v \in |C|} \theta_v \cdot v \) satisfying the following conditions:

- \( \theta_v \neq 0 \) for finitely many \( v \in |C| \),
- for a fixed \( \theta \neq 0 \), the cardinality of \( \{ v \in |C| \mid \theta_v = \theta \} \) equals \( N_{\theta} \),
- for each \( v \in |C| \) the restriction \( f|_{\text{Spec} \mathfrak{o}_v} : \text{Spec} \mathfrak{o}_v \to X/G \) defines a point in \( L^F X/L^+ G \).

**Lemma 3.1.6.** The substack \( M^{\hat{\Theta}}_\lambda \) is smooth and locally closed in \( M_X \).

We defer the proof of Lemma 3.1.6 to §A.3 of the appendix.

**Proposition 3.1.7.** Let \( S \) denote the collection of connected components of \( M^{\hat{\Theta}}_\lambda \), ranging over all \( \hat{\Theta} \in \text{Sym}^\infty(c_X - 0) \). Then \( S \) is a Whitney stratification of \( M_X \).

By a stratification we mean a collection of locally closed substacks that form a disjoint union on \( k \)-points and such that the closure of any stratum is a union of strata. The stratification is Whitney if the strata are smooth and every pair of strata satisfies Whitney’s condition B. (This only makes sense if the characteristic of \( k \) is zero; in positive characteristic, see §3.1.9 below.)

The proof of Proposition 3.1.7 is given in §A.4.7. We call this the fine stratification of \( M_X \).

**Remark 3.1.8.** If \( X \) is affine and homogeneous, then \( C_0 \cap V = 0 \) so the stratification is trivial, consisting of the single smooth stratum \( M_X \) itself.

---

\[ \text{We say that a stratification on an algebraic stack } M \text{ locally of finite type is Whitney if the stratification is Whitney after pullback along any (equivalently all) smooth cover of } M \text{ by a scheme.} \]
3.1.9. Let $D^b_{\mathcal{O}(\mathcal{M})}(\mathcal{M}_X) := D^b_S(\mathcal{M}_X, \mathcal{Q}_\ell)$ denote the subcategory of bounded $S$-constructible complexes, i.e., the usual cohomology sheaf $H^i(\mathcal{F})$ is a local system of finite rank for all $i \in \mathbb{Z}$ and $S \in S$. As explained in [BBDG18], the category $D^b_{\mathcal{O}(\mathcal{M})}(\mathcal{M}_X)$ has a perverse $t$-structure. Let $P_{\mathcal{O}(\mathcal{M})}(\mathcal{M}_X)$ denote the heart of this $t$-structure, i.e., this is the abelian subcategory of all perverse sheaves that are $S$-constructible. In particular, the IC complex of the closure of any stratum $\mathcal{M}_X$ is an object of $P_{\mathcal{O}(\mathcal{M})}(\mathcal{M}_X)$. When $k$ has positive characteristic, this is the condition on $S$ that we need (in place of the Whitney condition).

3.2. Toric case. If we apply the definitions above to the special case where $G$ is replaced by the torus $T_X$ and $X$ is replaced by the toric variety $X/\mathbb{N}$, we obtain the space

$$\mathcal{A} = \text{Maps}^\circ(C, (X/\mathbb{N})/T_X)$$

of maps generically landing in $T_X/T_X = \text{pt}$.

The stack $\mathcal{A}$ has been previously studied in [BNS16, §3] as a model for the formal arc space of the toric variety $X/\mathbb{N}$ (in particular, $\mathcal{A}$ turns out to be representable by a scheme). We review the relevant properties below.

For any $N \in \mathbb{N}$, we have the $N$th symmetric product $C(N)$ of $C$, which identifies with the Hilbert scheme $\text{Hilb}^N(C)$ parametrizing relative effective divisors in $C$ of degree $N$. Let $\text{Sym} C$ denote the disjoint union $\bigsqcup_{N \in \mathbb{N}} C(N)$ (where $C(0) = \text{pt}$).

Example 3.2.1. Observe that $\text{Maps}^\circ(C, \mathbb{A}^1/\mathbb{G}_m)$ sends a test scheme $S$ to the set of relative effective Cartier divisors on $C \times S$, i.e., $\text{Maps}^\circ(C, \mathbb{A}^1/\mathbb{G}_m) \cong \text{Sym} C$. Addition of divisors gives $\text{Sym} C$ the structure of a monoid.

Let $c_X^\vee = \text{Hom}(c_X, \mathbb{N})$ denote the monoid dual to $c_X$, so $k[X/\mathbb{N}]$ is the semigroup algebra of $c_X^\vee$. Then there is an isomorphism

$$\mathcal{A} \cong \text{Hom}(c_X^\vee, \text{Sym} C)$$

where the right hand side represents homomorphisms of monoids in the category of schemes. A $k$-point of $\mathcal{A}$ is a formal finite sum

$$\sum_{v \in |C|} \lambda_v \cdot v$$

where $\lambda_v$ is an element of the dual monoid $c_X$ and $\lambda_v = 0$ for all but finitely many $v$.

3.2.2. The stratification described in §3.1.5 takes here the following form: For any $\mathfrak{P} \in \text{Sym}^\infty(c_X - 0)$ there is a natural map

$$\tilde{C}^{\mathfrak{P}} \hookrightarrow \mathcal{A},$$

where the image consists of the $k$-points $\sum_{v \in |C|} \lambda_v \cdot v$ such that the unordered multiset of nonzero $\lambda_v$, counted with multiplicities, coincides with $\mathfrak{P}$.

Proposition 3.2.3 ([BNS16, Proposition 3.5]).

(i) The maps $\tilde{C}^{\mathfrak{P}} \hookrightarrow \mathcal{A}$ are locally closed embeddings, and the collection of such embeddings over all $\mathfrak{P} \in \text{Sym}^\infty(c_X - 0)$ forms a stratification of $\mathcal{A}$.

(ii) $C^{\mathfrak{P}'}$ lies in the closure of $C^{\mathfrak{P}}$ if and only if $\mathfrak{P}$ refines $\mathfrak{P}'$.

(iii) The irreducible components of $\mathcal{A}$ are in bijection with the closures of $\tilde{C}^{\mathfrak{P}}$ for $\mathfrak{P} \in \text{Sym}^\infty(\text{Prim}(C_0))$. 

Corollary 3.2.4 ([BNS16, Corollary 3.6]). For $\lambda \in \mathfrak{c}_X$, let 
\[ A^{\lambda} \subset A \]
denote the subscheme whose $k$-points consist of all $\sum_{v \in [C]} \lambda_v \cdot v$ such that $\sum_v \lambda_v = \lambda$. Then $A^{\lambda}$ is a connected component of $A$, and this gives a bijection 
\[ \pi_0(A) \cong \mathfrak{c}_X. \]

Remark 3.2.5. If $\mathfrak{c}_X$ is a free monoid with basis $\{\nu_i\}$, then for $\lambda = \sum_i N_i \nu_i$ we have $A^{\lambda} = \prod_i C(N_i)$. The bases for the Zastava spaces in [BFGM02, §2.1] take this form.

3.2.6. Convolution product. The toric variety $X//N$ has the natural structure of a commutative algebraic monoid. The multiplication operator on $X//N$ induces a finite map 
\[ m_A : A^{\lambda_1} \times A^{\lambda_2} \to A^{\lambda_1 + \lambda_2}. \]

If we have complexes $\mathcal{F}_i \in D^b_c(A^{\lambda_i})$, $i = 1, 2$, we define their convolution by 
\[ \mathcal{F}_1 \star \mathcal{F}_2 := m_{A,\lambda}(\mathcal{F}_1 \boxtimes \mathcal{F}_2) \in D^b_c(A^{\lambda_1 + \lambda_2}). \]

3.3. Zastava model. For the rest of this paper we assume that $B$ acts simply transitively on $X^o$. This implies that $T_X = T$ and $\Lambda_X = \Lambda_G$, so we will use the notation interchangeably.

We introduce a special case of the model used in [GN10, Part III], which is based on a general pattern pointed out by Drinfeld (see [Dri18, §4.2–4.4]). These are a generalization of the Zastava spaces introduced by Finkelberg–Mirković in [FM99, FFKM99, BFGM02], and we will henceforth call them the Zastava model for $X$.

The Zastava model for $X$ is defined as 
\[ \mathcal{Y} = \mathcal{Y}_X = \text{Maps}_{\text{gen}}(C, X/B \supset \text{pt}), \]
the stack of maps $C \times S \to X/B$ generically landing in $X^o/B = \text{pt}$.

Applying $\text{Maps}(C, ?/T)$ to the natural map $X/N \to X//B$ induces a map 
\[ \pi : \mathcal{Y} \to A. \]

For $\lambda \in \mathfrak{c}_X$, let $\mathcal{Y}^{\lambda}$ denote the preimage of $A^{\lambda}$ under $\pi$.

We show in Proposition 3.7.2 below that $\mathcal{Y}$ is representable by a scheme locally of finite type over $k$. This was predicted by Drinfeld [Dri18, Conjecture 4.2.3] in a more general setting.

Example 3.3.1. Let $X = G_m \setminus \text{GL}_2$ where $G_m$ is embedded as $(1, \cdot)$. Then $\tilde{G}_X = \tilde{G} = \text{GL}_2$ and $\tilde{\Lambda}_X = \tilde{\Lambda}_G = \mathbb{Z}^2$ with standard basis $\tilde{\varepsilon}_1, \tilde{\varepsilon}_2$. The $B$-orbits on $X$ are the same as $G_m$-orbits on $G/B = \mathbb{P}^1$, so there are three orbits: $G_m, \{0\}, \{\infty\}$. These correspond to $X^o$ and two colors $D^+, D^- \subset X$, respectively. We have $\tilde{\nu}_{D^+} = \tilde{\varepsilon}_1, \tilde{\nu}_{D^-} = -\tilde{\varepsilon}_2$ and $\mathfrak{c}_X = \mathbb{N}^2$ is the free monoid generated by $\tilde{\nu}_{D^+}, \tilde{\nu}_{D^-}$. Note that $\tilde{\nu}_{D^+} + \tilde{\nu}_{D^-} = \hat{0}$ is the simple coroot.

Since $X$ is affine homogeneous, $\mathcal{M}_X = \text{Bun}_H = \text{Bun}_1$ is the moduli stack of line bundles. The Zastava model is 
\[ \mathcal{Y} = \text{Maps}_{\text{gen}}(C, G_m \setminus \text{GL}_2/B \supset \text{pt}) = \text{Maps}_{\text{gen}}(C, G_m \setminus \mathbb{P}^1 \supset \text{pt}). \]
This is the stack parametrizing two line bundles $\mathcal{L}, \mathcal{A}$ on $C$ and a fiberwise injective map of vector bundles $\sigma : \mathcal{L} \hookrightarrow \mathcal{O}_C \oplus \mathcal{A}$ such that both coordinates $\sigma_1 : \mathcal{L} \hookrightarrow \mathcal{O}_C$ and $\sigma_2 : \mathcal{L} \hookrightarrow \mathcal{A}$ are generically nonzero. Thus $\sigma_1, \sigma_2$ are equivalent to two effective Cartier divisors $D_1, D_2$ which

"Zastava" is Croatian for "flag".
give \( \mathcal{L} = \mathcal{O}(-D_1) \) and \( \mathcal{A} = \mathcal{O}(D_2 - D_1) \). The condition that \( \sigma = (\sigma_1, \sigma_2) \) is fiberwise injective is equivalent to saying that the supports of \( D_1, D_2 \) are disjoint. Therefore we have an identification

\[
\mathcal{Y}_{\mathbb{G}_m} \setminus \text{GL}_2 = \text{Sym} \, C \times C = \bigsqcup_{(n_1, n_2) \in \mathbb{N}^2} C(n_1) \times C(n_2).
\]

Meanwhile \( A_{\mathbb{G}_m} \setminus \text{GL}_2 = \text{Sym} \, C \times \text{Sym} \, C = \bigsqcup_{n \geq 2} C(n_1) \times C(n_2) \). In this case \( \mathcal{Y} \to \mathcal{A} \) is the natural open embedding, and \( \mathcal{Y}^{n_1\nu_{D+} + n_2\nu_{D-}} = C(n_1) \times C(n_2) \) is connected. The map \( \mathcal{Y} \to M_X \) forgetting the \( B \)-structure corresponds to \( (D_1, D_2) \mapsto \mathcal{O}(D_2 - D_1) \).

Note that for the above embedding of \( \mathbb{G}_m \to \text{GL}_2 \), the open \( B \)-orbit is the orbit of \( (1, 1) \).

In particular \( X^o \) does not contain the identity coset. If we conjugate \( \mathbb{G}_m \) to the embedding \( \{1 - a \} \), then we may take the base point \( x_0 = 1 \).

**Example 3.3.2.** In the above example we could instead replace \( \text{GL}_2 \) by \( G = \text{PGL}_2 \) and \( H = \mathbb{G}_m \) becomes the split torus inside \( \text{PGL}_2 \). Then we still have \( X = \mathbb{G}_m \setminus \text{PGL}_2 \) affine spherical with \( \mathcal{G}_X = G = \text{SL}_2 \) and two colors \( D^+, D^- \). However now \( \tilde{A}_X = \tilde{A}_C = \mathbb{Z} \mathbb{Q} \) and \( \tilde{\nu}_{D+} = \tilde{\nu}_{D-} = \frac{\pi}{2} \).

The space \( \mathcal{Y}_{\mathbb{G}_m} \setminus \text{GL}_2 \) still identifies with \( \text{Sym} \, C \times \text{Sym} \, C \). However now \( A_{\mathbb{G}_m} \setminus \text{GL}_2 = \text{Sym} \, C \) with \( A^n = C(n) \). Then \( \mathcal{Y}^{n_2}_m \setminus \text{GL}_2 = \bigsqcup_{n_1 + n_2 = n} C(n_1) \times C(n_2) \) and the map \( \mathcal{Y} \to \mathcal{A} \) corresponds to addition of divisors.

Note that \( M_X = \text{Bun}_1 \) and \( C(n_1) \times C(n_2) \) maps to the component \( \text{Bun}_{n_2 - n_1} \) of degree \( n_2 - n_1 \) line bundles. Thus while \( \mathcal{Y}^{n_2} \) is not connected, fixing a connected component of \( \text{Bun}_1 \) determines the connected component of \( \mathcal{Y}^{n_2} \).

### 3.4. Graded factorization property

Note that our assumption on \( X^o \) implies that \( X^o / B = \text{pt} \) is a dense open substack of \( X / B \). In the language of [Dri18, §4.2.1], the stack \( X / B \) is pointy. Drinfeld observed that maps from a curve to a pointy stack will have local behavior with respect to \( C \) (compared to [Dri18], we are in the special setting where we have a group \( B \) acting on \( X \), not just a groupoid).

Let \( \tilde{\lambda} = \tilde{\lambda}_1 + \tilde{\lambda}_2 \) with \( \tilde{\lambda}_i \in \mathfrak{c}_X \) and let us denote by \( A^{\tilde{\lambda}_1} \times A^{\tilde{\lambda}_2} \) the open subset of the direct product \( A^{\tilde{\lambda}_1} \times A^{\tilde{\lambda}_2} \) consisting of \( \alpha_1, \alpha_2 : C \to (X / N) / T \) such that the supports of \( C - \alpha_1^{-1}(\text{pt}) \) and \( C - \alpha_2^{-1}(\text{pt}) \) are disjoint. We have a natural étale map \( A^{\tilde{\lambda}_1} \times A^{\tilde{\lambda}_2} \to A^{\lambda} \).

**Proposition 3.4.1.** The scheme \( \mathcal{Y} \) has the graded factorization property, in the sense that there there is a natural isomorphism

\[
\mathcal{Y}_{\tilde{A}^{\lambda_1}} \times (A^{\tilde{\lambda}_1} \times A^{\tilde{\lambda}_2}) \cong (\mathcal{Y}_{\tilde{A}^{\lambda_1}} \times \mathcal{Y}_{\tilde{A}^{\lambda_2}})_{A^{\lambda_1} \times A^{\lambda_2}}.
\]

**Proof.** Let \( y_1, y_2 : C \times S \to X / B \) be \( S \)-points of \( \mathcal{Y}_{\tilde{A}^{\lambda_1}} \), \( \mathcal{Y}_{\tilde{A}^{\lambda_2}} \), respectively. Let \( U_i = y_i^{-1}(\text{pt}) \subset C \times S \); the condition that \( (\pi(y_1), \pi(y_2)) \in A^{\tilde{\lambda}_1} \times A^{\tilde{\lambda}_2} \) is equivalent to requiring that \( U_1 \cup U_2 = C \times S \). Then \( y_1 \left|_{U_1 \cap U_2} \cong y_2 \right|_{U_1 \cap U_2} : U_1 \cap U_2 \to \text{pt} \) provides a gluing data for \( y_1, y_2 \) on the covering of \( C \times S \) by \( U_1 \) and \( U_2 \). Since \( X / B \) is a stack, the gluing data descends to a map \( y : C \times S \to X / B \) that sends \( U_1 \cap U_2 \) to \( \text{pt} \). This defines \( y \in \mathcal{Y}(S) \). The map in the opposite direction is constructed in the same way and they are mutually inverse. \( \Box \)

We will henceforth use the notation \( \mathcal{Y}_{\tilde{A}^{\lambda_1} \times \tilde{A}^{\lambda_2}} \) to denote \( (\mathcal{Y}_{\tilde{A}^{\lambda_1}} \times \mathcal{Y}_{\tilde{A}^{\lambda_2}})_{A^{\lambda_1} \times A^{\lambda_2}} \).

### 3.5. Global-to-Zastava yoga

We have a map \( \mathcal{Y} \to M_X \) by forgetting the \( B \)-structure. More precisely, we have an open embedding

\[
\mathcal{Y} \hookrightarrow M_X \times \text{Bun}_G \times \text{Bun}_B.
\]
Although the natural map \( \text{Bun}_B \to \text{Bun}_C \) is in general not smooth, it is smooth over a large enough open substack: consider \( T \) as the Levi quotient of \( B^- \). Let \( n^- \) denote the Lie algebra of \( N^- \) viewed as a \( T \)-module. Define the open substack \( \text{Bun}_T^c \subseteq \text{Bun}_T \) to consist of those \( T \)-bundles \( \mathcal{P}_T \) for which \( H^1(C, V \times^T \mathcal{P}_T) = 0 \), for all \( T \)-modules \( V \) which appear as subquotients of \( n^- \). Let \( \text{Bun}_B' \) be the preimage of \( \text{Bun}_T^c \) under the natural projection \( \text{Bun}_B \to \text{Bun}_T \).

For \( \mu \in \Lambda_T \), let \( \text{Bun}_T^\mu \) denote the corresponding connected component of \( \text{Bun}_T \) of degree \( \mu \), and let \( \text{Bun}_B^\mu \) (resp. \( \text{Bun}_B^{\mu^\vee} \)) be its preimage in \( \text{Bun}_B \) (resp. \( \text{Bun}_B^\mu \)). Note that by Riemann–Roch, \( \text{Bun}_B^{\mu^\vee} = \text{Bun}_B^{-\mu} \) if \( \langle \alpha_i, \mu \rangle > 2g - 2 \) for all simple roots \( \alpha_i \), where \( g \) is the genus of \( C \).

We say that \( \mu \) is “large enough” if \( \langle \alpha_i, \mu \rangle > N \) for all simple roots \( \alpha_i \) and some \( N \gg 0 \).

Lemma 3.5.1 ([BFGM02, Lemma 3.7], [GN10, Lemma 14.2.1], [DS95]). The restriction of \( \text{Bun}_B \to \text{Bun}_C \) to \( \text{Bun}_B^\mu \) is smooth. Any open substack \( U \subseteq \text{Bun}_C \) of finite type is contained in the image of \( \text{Bun}_B^{\mu^\vee} \) for \( \mu \) large enough, and the fibers of \( \text{Bun}_B^{\mu^\vee} \to \text{Bun}_C \) over \( U \) are geometrically connected.

Under our conventions, the composition \( y^\lambda \to \text{Bun}_B \to \text{Bun}_T \) lands in the connected component \( \text{Bun}_T^\lambda \).

Corollary 3.5.2. (i) The map \( y^\mu \to \mathcal{M}_X \) is smooth with geometrically connected fibers (when nonempty) for \( \mu \) large enough.

(ii) Any k-point of \( \mathcal{M}_X \) lies in the image of \( y^\mu \) for all \( \mu \) in a translate of \( \Lambda^\text{pos} \).

Proof. We have an open embedding \( y^\mu \hookrightarrow \mathcal{M}_X \times_{\text{Bun}_C} \text{Bun}_B^{-\mu} \), so (i) follows from Lemma 3.5.1 by base change. To show (ii), we consider the fiber of \( y \to \mathcal{M}_X \) on \( k \)-points:

A point \( f \in \mathcal{M}_X(k) \) is equivalent to a datum \( (\mathcal{P}_G, \sigma : C \to X \times^G \mathcal{P}_G) \). By [Ste65], there exists an open subscheme \( U \subseteq C \) on which \( \mathcal{P}_G|_U \) can be trivialized. If we fix such a trivialization, then \( \sigma|_U \) identifies with a section \( U \to H \backslash G \). Since \( H \backslash G \) is spherical, \( \sigma(U) \) intersects the open orbit of some Borel \( k \)-subgroup of \( G \). This Borel corresponds to a point in \( (G/B)(k) \subset (G/B)(k) \), where \( k = k(C) \). Using our fixed trivialization of \( \mathcal{P}_G|_U \), we get a section \( \text{Spec} \mathbb{k} \to \mathcal{P}_G \times^G G/B \), which extends to a section \( C \to \mathcal{P}_G \times^G G/B \) since \( G/B \) is proper. The latter is equivalent to giving a \( B \)-structure \( \mathcal{P}_B \) on \( \mathcal{P}_G \). By construction \( (\mathcal{P}_B, \sigma) \) satisfies the generic condition for it to lie in \( y(k) \).

Let us fix an arbitrary lift of \( (\mathcal{P}_G, \sigma) \) to \( (\mathcal{P}_B^\mu, \sigma) \in y(k) \) and fix a trivialization of \( \mathcal{P}_B^\mu|_{\text{Spec} \mathbb{k}} \). Then this lift corresponds to \( 1B \in (G/B)(k) \) and all other lifts to \( y(k) \) correspond to the \( H(k) \)-orbit of \( 1B \). We are concerned with the possible degrees of \( \mathcal{P}_B \) for \( (\mathcal{P}_B, \sigma) \in y(k) \) above \( (\mathcal{P}_G, \sigma) \). For a simple root \( \alpha \) of \( G \), let \( P_\alpha \) denote the corresponding minimal parabolic in \( G \). Then the \( (H \cap P_\alpha)-\text{orbit} \) on \( 1 \in P_\alpha/B = \mathbb{P}^1 \) is open, so in particular it contains \( \mathbb{G}_m \subset \mathbb{P}^1 \). Therefore the \( H(k) \)-orbit of \( 1B \in (G/B)(k) \) contains \( \mathbb{G}_m(k) \subset (P_\alpha/B)(k) \).

By the Riemann–Roch theorem, we deduce that for any \( N \gg 0 \), there is a lift \( \mathcal{P}_B \) of degree \( -(\tilde{\mu}_1 + N\lambda) \), where \( \tilde{\mu}_1 \) is the degree of \( \mathcal{P}_B^\mu \). We conclude that there exists a lift \( (\mathcal{P}_B, \sigma) \in y^\mu(k) \) for any \( \mu \) in a certain translate of \( \Lambda^\text{pos} \).

3.5.3. It is not in general true that the natural map \( y^\lambda \to \mathcal{M}_X \) is smooth for arbitrary \( \lambda \). However, the following well-known argument (cf. [GN10, Theorem 16.2.1]) shows that any neighborhood of a point in \( y^\lambda \) is smooth locally isomorphic to a neighborhood of a point in \( \mathcal{M}_X \):

Let \( \lambda \in \mathcal{C}_X \) be arbitrary. Since \( \Lambda^\text{pos}_G \subseteq \mathcal{C}_0 \), we can always find \( \mu \in \Lambda^\text{pos}_G \) large enough such that \( \lambda + \mu \) is also large enough. Let \( y^{\mu, 0} \) denote the preimage of \( \mathcal{M}_X^\mu = \text{Bun}_B^\mu \) under the smooth map \( y^\mu \to \mathcal{M}_X \). Then \( y^{\mu, 0} \) is smooth and the first projection \( y^\lambda \times y^{\mu, 0} \to y^\lambda \)
is smooth. On the other hand, by the graded factorization property (Proposition 3.4.1), there
is a natural étale map
\[ y^\lambda \times y^{\bar{\mu},0} \to y^{\lambda + \bar{\mu}}. \]
We can compose this with the smooth map \( y^{\lambda + \bar{\mu}} \to \mathcal{M}_X \) to get a smooth map \( y^\lambda \times y^{\bar{\mu},0} \to \mathcal{M}_X \).

To summarize, we have constructed:

**Lemma 3.5.4.** For any \( \lambda \in \epsilon_X \) and any \( \bar{\mu} \in \hat{\Lambda}^\text{pos}_G \) large enough, there is a correspondence
\[ y^\lambda \leftarrow y^\lambda \times y^{\bar{\mu},0} \to \mathcal{M}_X \]
where the left arrow is smooth surjective, and the right arrow is smooth.

3.6. **Stratification of the Zastava model.** We stratify \( \hat{\mathcal{Y}}_\lambda \) according to the fine stratification of \( \mathcal{M}_X \): for a partition \( \Theta \in \text{Sym}^\infty (\epsilon_X - 0) \) and \( \lambda \in \epsilon_X \), define the stratum
\[ \hat{\mathcal{Y}}^\lambda,\Theta := \hat{\mathcal{Y}}^\lambda \times \mathcal{M}^\Theta_X. \]

Abbreviate \( \hat{\mathcal{Y}}^\lambda,\Theta := \hat{\mathcal{Y}}^{\lambda,\Theta} \).

**Proposition 3.6.1.** The stratum \( \hat{\mathcal{Y}}^\lambda,\Theta \) is a smooth locally closed subscheme of \( \hat{\mathcal{Y}}^\lambda \).

**Proof.** By Lemma 3.5.4, there exists \( \bar{\mu} \in \hat{\Lambda}_X \) such that there is a smooth correspondence
\[ y^\lambda \leftarrow y^\lambda \times y^{\bar{\mu},0} \to \mathcal{M}_X \]
where the left arrow is surjective. Note that by definition of \( \mathcal{M}^\Theta_X \), the preimage of \( \mathcal{M}^\Theta_X \) in \( y^\lambda \times y^{\bar{\mu},0} \) is isomorphic to \( y^\lambda,\Theta \times y^{\bar{\mu},0} \) since \( y^{\bar{\mu},0} \) consists of maps \( C \to X/\mathbb{L} + G \) which can only define points in \( L^0 X/\mathbb{L} + G \) upon restriction to \( \mathfrak{o}_v \) for any \( v \in |C| \). Therefore we get a smooth correspondence
\[ (3.5) \quad y^\lambda,\Theta \leftarrow y^\lambda,\Theta \times y^{\bar{\mu},0} \to \mathcal{M}^\Theta_X \]
where the left arrow is still surjective. Now smoothness of \( y^\lambda,\Theta \) follows from smoothness of \( \mathcal{M}^\Theta_X \) (Lemma 3.1.6). \( \square \)

We call the collection of connected components of \( y^\lambda,\Theta \) the fine stratification of \( y^\lambda \). By the smooth correspondence (3.5) above and Proposition 3.1.7, this is a Whitney stratification (in fact the Zastava model is used in the proof of loc. cit.).

Note that for a fixed \( \lambda \), many of the \( y^\lambda,\Theta \) are empty.

3.7. **Relation to the affine Grassmannian.** Let \( \text{Gr}_{G,Sym} C \to Sym C \) denote the following version of the Beilinson–Drinfeld affine Grassmannian: an \( S \)-point consists of a relative effective Cartier divisor \( D \subset C \times S \) and a \( G \)-bundle \( \mathcal{P}_{G} \) on \( C \times S \) together with a trivialization \( \mathcal{P}_{G}|_{C \times S - D} \cong \mathcal{P}_{G}^0|_{C \times S - D} \) where \( \mathcal{P}_{G}^0 \) is the trivial \( G \)-bundle. For any linear algebraic group \( G \), the functor \( \text{Gr}_{G,Sym} C \) is representable by an ind-scheme, ind-of finite type over \( Sym C \) (cf. [BD96], [Zhu17, Theorem 3.1.3]).

In particular, we can consider the ind-scheme \( \text{Gr}_{B,Sym} C \). Let \( \text{Gr}_{B,C(N)} \) denote the preimage over \( C^{(N)} \).
3.7.1. Choose some $\delta \in \Lambda_X$ that lies on the interior of the cone dual to $C_0(X)$, so $(\delta, \lambda) > 0$ for any nonzero $\lambda \in C_0(X)$. Let $f_\lambda \in \mathcal{O}[X(B)]$ denote the corresponding $\delta$-eigenfunction. Then $f_\lambda$ induces a map $X/N \to \Lambda^1$, which in turn induces a map $\mathcal{A} \to \text{Sym} \mathcal{C}$ sending $\mathcal{A}^\lambda \to C^{((\delta, \lambda))}$. We can map\(^\footnote{The effective Cartier divisor cut out by $f_\delta$ has the property that the complement of its support in $X$ equals $X^\circ$. In this guise, the map $\mathcal{Y} \to \text{Sym} \mathcal{C}$ we have constructed coincides with the one described in [Dri18, Remark 4.2.6].}

\begin{equation}
\mathcal{Y}^\lambda \to \text{Gr}_{B, \mathcal{C}^{((\delta, \lambda))}}
\end{equation}

as follows: let $y : C \times S \to X/B$ be an $S$-point of $\mathcal{Y}$. Let $D \subset C \times S$ be the relative effective divisor corresponding to the image of $\pi(y) \in \mathcal{A}(S)$ under the map $\mathcal{A} \to \text{Sym} \mathcal{C}$. Since $\delta$ was chosen in the interior of the dual cone of $C_0(X)$, we have $C \times S - D = y^{-1}(\mathfrak{pt}) := U$. Thus $y$ defines a $B$-bundle $\mathcal{P}_B$ on $C \times S$ together with a section $U \to X^0 \times B \mathcal{P}_B \cong \mathcal{P}_B$, i.e., a trivialization of $\mathcal{P}_B|_U$. The datum $(D, \mathcal{P}_B, \mathcal{P}_B|_U \cong \mathcal{P}_B|_U)$ defines an $S$-point of $\text{Gr}_{B, \text{Sym} \mathcal{C}}$.

**Proposition 3.7.2.** The map \((3.6)\) is a closed embedding. Moreover, the stack $\mathcal{Y}$ is representable by a scheme locally of finite type over $k$, and for fixed $\lambda \in \tau_X$, the scheme $\mathcal{Y}^\lambda$ is of finite type over $k$. Consequently, the map $\pi : \mathcal{Y} \to \mathcal{A}$ is schematic of finite type.

**Proof.** First we show that \((3.6)\) is a closed embedding. Fix a map $S \to \text{Gr}_{B, \text{Sym} \mathcal{C}}$ corresponding to a pair $(D, \mathcal{P}_B)$ and a trivialization of $\mathcal{P}_B$ away from $D$. A trivialization of $\mathcal{P}_B$ on $C \times S - D$ is equivalent to a section $\sigma_0 : C \times S - D \to \mathcal{P}_B \cong X^0 \times B \mathcal{P}_B$. The fiber of $\mathcal{Y} \to \text{Gr}_{\text{Sym} \mathcal{C}}$ over $S$ parametrizes commutative diagrams

\begin{equation}
\begin{array}{ccc}
C \times S' - D' & \xrightarrow{\sigma_0} & X^0 \times B \mathcal{P}_B \\
\downarrow & & \downarrow \\
C \times S' & \xrightarrow{\sigma} & X \times B \mathcal{P}_B
\end{array}
\end{equation}

where $S'$ is an $S$-scheme, $D' := D \times_S S'$, and $\sigma$ is a section over $C \times S$. Observe that $\sigma$ is uniquely determined by $\sigma_0$. By Lemma 3.7.3 below, the condition that $\sigma_0$ extends to $\sigma$ is closed in $S$.

We have shown that $\mathcal{Y}$ is representable by an ind-scheme ind-closed in $\text{Gr}_{B, \text{Sym} \mathcal{C}}$. On the other hand, we have a map $\mathcal{Y} \to \text{Bun}_B$ whose fiber over an $S$-point $\mathcal{P}_B \in \text{Bun}_B(S)$ is open in the space of sections $C \times S \to X \times B \mathcal{P}_B$ over $C \times S$. This space is representable by a scheme locally of finite type over $k$ ([FGI'05, Theorem 5.23]). Since $\text{Bun}_B$ is an algebraic stack, we conclude that $\mathcal{Y}$ is an algebraic stack representable by an ind-scheme. Hence $\mathcal{Y}$ is representable by a scheme. For fixed $\lambda \in \tau_X$, we now know that $\mathcal{Y}^\lambda$ is a closed subscheme of $\text{Gr}_{B, \mathcal{C}^{((\delta, \lambda))}}$, which is ind-of finite type. It follows that $\mathcal{Y}^\lambda$ is of finite type over $k$. The other assertions all follow. \(\square\)

**Lemma 3.7.3.** Let $S$ be a test scheme and $D \subset C \times S$ a relative effective divisor. Let $X$ be a scheme affine of finite presentation over $C \times S$. Suppose that there exists a section $\sigma : C \times S - D \to X$ over $C \times S$. Then the functor sending $S'$ to maps $S' \to S$ such that $\sigma$ extends to a regular map on $C \times S'$ is representable by a closed subscheme of $S$.

**Proof.** The map $\sigma$ is equivalent to a map of $\mathcal{O}_{C \times S}$-algebras $\mathcal{O}_X \to \mathcal{O}_{C \times S - D}$. Given $S' \to S$, the condition that $\sigma$ extends to $C \times S'$ is equivalent to requiring the image of $\mathcal{O}_X \to \mathcal{O}_{C \times S - D}$ to land in $\mathcal{O}_{C \times S'} \subset \mathcal{O}_{C \times S' - D'}$ after base change to $S'$, where $D' := D \times_S S'$.

The claim is local in $S$, so
we may assume that \( \mathcal{O}_X \) is surjected onto by \( \text{Sym}_{\mathcal{O}_{C \times S}}(\mathcal{E}^\vee) \) for some vector bundle \( \mathcal{E} \) on \( C \times S \). Then we just need the composed \( \mathcal{O}_{C \times S} \)-linear map \( \mathcal{E}^\vee \to \mathcal{O}_{C \times S - D} \to \mathcal{O}_{C \times S - D} / \mathcal{O}_{C \times S} \) to vanish after base change to \( S' \). Since \( \mathcal{E}^\vee \) is coherent, the image of this map is contained in a submodule \( \mathcal{T} = \mathcal{O}(m \cdot D) / \mathcal{O}_{C \times S} \) for some integer \( m \geq 0 \). The projections \( p : C \times S \to S, p' : C \times S' \to S' \) are proper, and we are considering when an element in \( H^0 p'_! (\mathcal{E} \otimes_{\mathcal{O}_{C \times S}} \mathcal{T} \otimes_{\mathcal{O}_S} \mathcal{O}_S) \) vanishes. Note that \( p_*(\mathcal{E} \otimes_{\mathcal{O}_{C \times S}} \mathcal{T}) \) is finite locally free as an \( \mathcal{O}_S \)-module. By cohomology and base change we are reduced to asking when an element of \( p_*(\mathcal{E} \otimes \mathcal{T}) \) vanishes after base change to \( S' \). This is a closed condition on \( S \).

Remark 3.7.4 (Open curves). The graded factorization property of \( Y^1 \) implies that the geometry of \( Y^1 \) is purely local with respect to the curve \( C \). Therefore we could define

\[ Y(C) = \text{Maps}_{\text{gen}}(C, X/B \supset \text{pt}) \]

for any smooth curve \( C \) (not necessarily projective), and all the same properties would still hold. For example, in [FM99], [Dri18], the affine curve \( C = \mathbb{A}^1 \) is used.

3.7.5. Beauville–Laszlo’s theorem. Let \( S \) be an affine scheme and \( D \) a closed affine subscheme of \( C \times S \). Denote by \( \hat{C}_D \) the formal completion of \( C \times S \) along \( D \) and by \( C_D^\circ \) the spectrum of the ring of regular functions on \( \hat{C}_D \) (so \( C_D\) is an ind-affine formal scheme and \( C_D^\circ \) is the corresponding true scheme). Let \( C_D^\circ := C_D^\circ \to D \) denote the open subscheme.

There are maps \( \hat{p} : \hat{C}_D \to C \times S \) and \( i : C_D^\circ \to \hat{C}_D \). We will implicitly use the following fact in what follows:

Proposition 3.7.6 ([BD96, Proposition 2.12.6]). There exists a unique map \( p : C_D^\circ \to C \times S \) such that \( \hat{p} = p \circ i \).

To justify that \( Y \) is of local nature, we record the following consequence of the globalized version of Beauville–Laszlo’s theorem (cf. [BD96, Theorem 2.12.1], [BL95]). Let \( S \) be an affine scheme and \( D \subset C \times S \) a relative effective divisor. Proposition 3.7.6 implies there exists a map \( p : C_D^\circ \to C \times S \).

Lemma 3.7.7. Let \( X \) be any affine scheme with an action of an algebraic group \( B \) such that \( X/B \) is pointy, i.e., \( X \) has an open \( B \)-orbit \( X^o \) with \( X^o/B = \text{pt} \). Let \( C, S \) and \( D \) as above.

Then there is a natural equivalence between the following categories:

(i) the groupoid of \( (\mathcal{P}_B, \sigma) \) where \( \mathcal{P}_B \) is a \( B \)-bundle on \( C \times S \) and a section \( \sigma : C \times S \to X^o \times B \mathcal{P}_B \) that sends \( C \times S - D \) to \( X^o \times B \mathcal{P}_B \),

(ii) the groupoid of \( (\hat{\mathcal{P}}_B, \hat{\sigma}) \) where \( \hat{\mathcal{P}}_B \) is a \( B \)-bundle on \( \hat{C}_D \) and a section \( \hat{\sigma} : \hat{C}_D \to X^o \times B \hat{\mathcal{P}}_B \) that sends \( \hat{C}_D \) to \( X^o \times B \hat{\mathcal{P}}_B \).

Proof. The functor from (i) to (ii) is just pullback along \( p \). To define the functor from (ii) to (i) we descend along the covering \( \hat{C}_D \sqcup (C \times S - D) \to C \times S \). The justification for this is Beauville–Laszlo’s theorem (cf. [BD96, Theorem 2.12.1]). First, \( \hat{\sigma} \) induces a section \( \hat{C}_D \to X^o \times B \hat{\mathcal{P}}_B \cong \mathcal{P}_B \). Then we can “descend” \( \hat{\mathcal{P}}_B \) to a \( B \)-bundle \( \mathcal{P}_B \) on \( C \times S \) with a section \( C \times S - D \to \mathcal{P}_B \) (which is equivalent to a trivialization of \( \mathcal{P}_B|_{C \times S - D} \)). The section \( \hat{\sigma} \) is equivalent to a map of quasi-coherent \( \mathcal{O}_{\hat{C}_D} \)-algebras \( \mathcal{O}_{X^o \times B \hat{\mathcal{P}}_B} \to \mathcal{O}_{\hat{C}_D} \) since \( X \) is affine. Again by [BD96, Theorem 2.12.1], this descends to a map of quasi-coherent \( \mathcal{O}_{C \times S} \)-algebras \( \mathcal{O}_{X^o \times B \mathcal{P}_B} \to \mathcal{O}_{C \times S} \) such that the restriction to \( C \times S - D \) factors through the trivialization \( \mathcal{O}_{X^o \times B \mathcal{P}_B} \cong \mathcal{O}_{\mathcal{P}_B} \to \mathcal{O}_{C \times S - D} \). By construction, the two functors are mutually inverse. \( \square \)
3.8. Theorem of Grinberg–Kazhdan, Drinfeld. We now justify why \( \mathcal{M}_X \) and \( \mathcal{Y} \) are indeed “models” for the formal arc space \( L^+X \). Since \( \mathcal{M}_X \) and \( \mathcal{Y} \) are smooth-locally isomorphic, it suffices to explain the latter.

**Definition 3.8.1.** A finite dimensional formal model of \( L^+X \) at \( \gamma_0 \in LX(k) \) is the formal completion \( \hat{Y}_y \) of a \( k \)-scheme of finite type \( Y \) at a point \( y \in Y \) equipped with an isomorphism of formal schemes

\[
\hat{L}^+X_{\gamma_0} \simeq \hat{Y}_y \times \hat{\mathbb{A}}^\infty,
\]

where \( \hat{\mathbb{A}}^\infty \) is the product of countably many copies of the formal disk \( \text{Spf } k[[t]] \).

Since \( X/B \supset \text{pt} \) is a pointy stack, Drinfeld’s proof [Dri18, §4.2-4.3] of the Grinberg–Kazhdan theorem essentially shows that the scheme \( \mathcal{Y} \) (which we have shown is a disjoint union of finite type schemes) explicitly satisfies the following:

**Theorem 3.8.2** (Grinberg–Kazhdan, Drinfeld). Fix an arc \( \gamma_0 : \text{Spec } k[[t]] \to X \) in \( L^+X(k) \) such that \( \gamma_0(\text{Spec } k(t)) \subset X^\circ \). Then there exists a point \( y \in \mathcal{Y}(k) \) such that the formal completion of \( \mathcal{Y} \) at \( y \) is a finite-dimensional formal model of \( L^+X \) at \( \gamma_0 \). More precisely, if \( \gamma_0 \) belongs to the stratum \( L^\theta X \), for \( \theta \in \mathcal{C}_X \), we can take \( y \) to be the point \( t^\theta \) in the central fiber \( \mathcal{Y}^\theta,t^\theta \) over any point \( v \in C \).

The definition of the central fiber \( \mathcal{Y}^\theta \subset \mathcal{G}_B \) is given below in §4.3, and \( t^\theta \) denotes the corresponding point in \( \mathcal{G}_B \). The significance of this point will become evident in Corollary 5.5.6(iii).

The statements all follow from the proof of [Dri18, §4]. We also give the same argument, with some notational changes, in the proof of Theorem 8.2.4.

**Remark 3.8.3.** The point \( y : C \to X/B \) can be chosen so that \( y^{-1}(\text{pt}) = C - v \) for a single point \( v \in |C| \). However it is essential, for the theorem to hold, that \( \mathcal{Y} \) contains maps with multiple points of \( C \) mapping to \( (X - X^0)/B \).

4. Compactification of the Zastava model

The map \( \pi : \mathcal{Y} \to \mathcal{A} \) defined in (3.3) is in general not proper, so for example we cannot apply the decomposition theorem. To rectify this, we introduce a compactification.

4.1. Basic properties. Let \( \overline{G/N} = \text{Spec } k[\overline{G/N}] \) denote the canonical affine closure of the quasi-affine variety \( G/N \). For an arbitrary connected reductive group \( G \), Drinfeld’s compactification \( \overline{\text{Bun}}_B \) is defined\(^{14}\) as the closure of \( \text{Bun}_B \) inside \( \text{Maps}_{\text{gen}}(C, \overline{G/N}/T \supset \text{pt}/B) \),

the stack parametrizing maps \( C \to G/\overline{G/N}/T \) that generically land in the open substack \( G\backslash(G/N)/T = \text{pt}/B \). (When \( [G,G] \) is simply connected, [BG02, Proposition 1.2.3] show that \( \text{Bun}_B \) is dense in \( \text{Maps}_{\text{gen}}(C, G\backslash(G/N)/T \supset \text{pt}/B) \).)

Consider the stack quotient \( X \times ^G \overline{G/N} := (X \times \overline{G/N})/G \), where \( G \) acts anti-diagonally. Then \( X/N = X \times ^G G/N \) is an open substack of \( X \times ^G \overline{G/N} \), so we also have the open substack \( \text{pt} = X^\circ/B \subset X/B \subset X \times ^G \overline{G/N}/T \). Define

\[
\overline{\mathcal{Y}} = (\mathcal{M}_X \times _{\text{Bun}_G} \overline{\text{Bun}}_B)^\circ \subset \text{Maps}_{\text{gen}}(C, X \times ^G \overline{G/N}/T \supset \text{pt})
\]

\( ^{14}\)The definition as a closure is only true in characteristic 0. In positive characteristic, see [ABB+05, §4.1], [Sch15, §7.2].
where the superscript \( ^o \) denotes the open substack of 
\[
\mathcal{M}_X \times \overline{\text{Bun}}_G \subset \text{Maps}_{\text{gen}}(C, X^G / \overline{G} / N / T \supset X^* / B)
\]
parametrizing maps generically landing in \( \text{pt} = X^o / B \). In particular, \( \overline{Y} \) is an algebraic stack locally of finite type. We can identify \( Y \equiv \overline{Y} \times_{\overline{\text{Bun}}_G} \text{Bun}_G \) as an open substack of \( \overline{Y} \). (If \( [G, G] \)

is simply connected, the containment in (4.1) is an equality.)

There is a natural map from \( X \times^G \overline{G} / N \) to
\[
(X \times \overline{G} / N) / G = \text{Spec } k[\overline{G} / G]^N.
\]
Since \( k[\overline{G} / G]^N = k[X] \), we deduce that \( X \times \overline{G} / N) / G = X / N \). Therefore we have a map \( X \times^G \overline{G} / N \to X / N \) extending the natural map \( X / N \to X / N \). Applying \( \text{Maps}(C, ? / T) \) to the former, we have constructed a map
\[
(4.2) \pi : \overline{Y} \to A
\]
extending \( \pi : Y \to A \). Let \( \overline{Y}^A \) denote the preimage of the subscheme \( A^\lambda \). The same proof as in Proposition 3.4.1 shows that \( \overline{Y} \) has the graded factorization property. We will see from Lemma 4.1.2 below that \( \overline{Y}^A \) is representable by a scheme of finite type over \( k \).

First, we show that \( \pi \) is indeed a compactification:

**Proposition 4.1.1.** The map \( \pi : \overline{Y} \to A \) is proper.

We proceed as in §3.7.1. Choose \( \delta \in \Lambda_X \) lying on the interior of the cone dual to \( C_0(X) \). Then \( \delta \) defines a map \( X / N \to A^\lambda \), which induces a map \( A \to \text{Sym } C \). This allows us to consider \( Y \) as a scheme over \( \text{Sym } C \). Proposition 3.7.2 gives a closed embedding \( Y \hookrightarrow \text{Gr}_{B, \text{Sym } C} \) over \( \text{Sym } C \).

We compose this with the natural map \( \text{Gr}_{B, \text{Sym } C} \to \text{Gr}_{G, \text{Sym } C} \) to get a map \( Y \to \text{Gr}_{G, \text{Sym } C} \).

We can extend this to a map
\[
(4.3) \quad \overline{Y} \to \text{Gr}_{G, \text{Sym } C}
\]
using the same idea as in the definition of (3.6). Namely, let \( y : C \times S \to X \times^G \overline{G} / N / T \) be an \( S \)-point of \( \overline{Y} \) and let \( D \subset C \times S \) denote the divisor it maps to. In particular, \( y \) defines a \( G \)-bundle \( \mathcal{P}_G \) on \( C \times S \) with a \( B \)-reduction on \( C \times S - D \). Since \( y(C \times S - D) = X^o / B = \text{pt} \), the \( G \)-bundle in fact admits a trivialization on \( C \times S - D \). The data of \( D, \mathcal{P}_G \), and the trivialization defines an \( S \)-point of \( \text{Gr}_{G, \text{Sym } C} \).

**Lemma 4.1.2.** The map \( \overline{Y} \to \text{Gr}_{G, \text{Sym } C} \times_{\text{Sym } C} A \) is a closed embedding.

Since \( \text{Gr}_{G, \text{Sym } C} \) is ind-proper over \( \text{Sym } C \) (cf. [Zhu17, Remark 3.1.4]), Proposition 4.1.1 follows from Lemma 4.1.2. We also deduce from the lemma that \( \overline{Y} \) is representable by a scheme, and each \( \overline{Y}^A \) is of finite type.

**Proof.** The discussion above really defines a map
\[
(4.4) \quad \text{Maps}_{\text{gen}}(C, X^G / \overline{G} / N / T \supset \text{pt}) \to \text{Gr}_{G, \text{Sym } C} \times_{\text{Sym } C} A,
\]
and \( \overline{Y} \hookrightarrow \text{Maps}_{\text{gen}}(C, X^G / \overline{G} / N / T \supset \text{pt}) \) is a closed embedding. Thus it suffices to prove that (4.4) is a closed embedding. Fix a test scheme \( S \). Let \( \mathcal{P}_G^\emptyset, \mathcal{P}_B^\emptyset, \mathcal{P}_G^T \) denote the respective trivial bundles on \( C \times S \). An \( S \)-point of \( \text{Gr}_{G, \text{Sym } C} \times_{\text{Sym } C} A \) consists of the data
\[
(\mathcal{P}_G, \mathcal{P}_T, D, \tau, \alpha)
\]
where $\mathcal{P}_G \in \text{Bun}_G(S)$, $\mathcal{P}_T \in \text{Bun}_T(S)$, $D \in \text{Sym}(C(S))$, a trivialization $\tau : \mathcal{P}_T^0|_{C \times S - D} \cong \mathcal{P}_G|_{C \times S - D}$, and a section $\alpha : C \times S \to (X//N)^T \mathcal{P}_T$ such that $(\mathcal{P}_T, \alpha) \in A(S)$ maps to $D$. In particular, this means that $\alpha$ induces a trivialization $\mathcal{P}_T^0|_{C \times S - D} \cong \mathcal{P}_T|_{C \times S - D}$. Using the identification $X^\circ \cong B$, we get a section

$$\sigma_0 : C \times S - D \to \mathcal{P}_T^0 \cong X^\circ \times \mathcal{P}_T^0 \hookrightarrow X \times \mathcal{P}_B = X \times \mathcal{P}_G^0.$$ 

The composition $\sigma := \tau \circ \sigma_0$ then defines a section $C \times S - D \to X^G \mathcal{P}_G$. On the other hand, the trivial $B$-bundle also corresponds to a section $\kappa_0 : C \times S - D \to \mathcal{P}_G^0 \times (G/N)$. Composing $\kappa_0$ with the trivialization $\alpha : \mathcal{P}_T^0|_{C \times S - D} \cong \mathcal{P}_T|_{C \times S - D}$, we get a section

$$\kappa : C \times S - D \to \mathcal{P}_G^0 \times \frac{G}{G/N} \times \mathcal{P}_T.$$

The datum $(\mathcal{P}_G, \mathcal{P}_T, \sigma, \kappa)$ defines an $S$-point of Maps$(C, X^G \mathcal{P}_G/N/T)$ if and only if $\sigma, \kappa$ both extend to regular maps on $C \times S$. Therefore the fiber of our chosen $S$-point over the map (4.4) parametrizes maps $S' \to S$ such that the base change of $\sigma, \kappa$ to $S'$ both extend to $C \times S'$. By Lemma 3.7.3, this fiber is represented by a closed subscheme of $S$ (here the key is that both $X$ and $G/N$ are affine).

**Remark 4.1.3.** We need the extra factor of $A$ in Lemma 4.1.2 which was not present in Proposition 3.7.2 because the map $\text{Gr}_B \to \text{Gr}_G$ is a bijection on $k$-points but pathological as a map of ind-schemes. Since $A$ embeds into $\text{Gr}_{T, \text{Sym}\, C}$, the lemma is really embedding $\overline{\mathcal{Y}}$ into $\text{Gr}_{G, \text{Sym}\, C} \times_{\text{Sym}\, C} \text{Gr}_{T, \text{Sym}\, C}$. The ind-scheme $\text{Gr}_T$ is pathological, although $(\text{Gr}_T)_{\text{red}}$ is a disjoint union of points.

**Example 4.1.4.** Let $X = \mathbb{G}_m \setminus \text{GL}_2$ as in Example 3.3.1. Then $\overline{\mathcal{Y}} = \text{Sym}\, C \times \text{Sym}\, C$ and $\overline{\mathcal{Y}} \to A$ is the identity morphism.

### 4.2. Stratification

We can uniquely write any $\hat{\nu} \in \hat{\Lambda}_G^{\text{pos}}$ as a sum $\hat{\nu} = \sum_{\alpha \in \Delta_G} n_{\alpha} \hat{\alpha}$ where $\Delta_G$ is the set of simple coroots and $n_{\alpha}$ are positive integers. Let $C_{\hat{\nu}} \colonequals \prod_{\alpha \in \Delta_G} C^{(n_{\alpha})}$ denote the corresponding partially symmetrized power of $C$. Recall that Drinfeld’s compactification $\overline{\text{Bun}}_B$ of $\text{Bun}_B$ has a stratification by *defect*, where the strata are given by locally closed embeddings

$$i_{\hat{\nu}} : C_{\hat{\nu}} \times \overline{\text{Bun}}_B^{+, \hat{\nu}} \hookrightarrow \overline{\text{Bun}}_B,$$

for $\hat{\nu} \in \hat{\Lambda}_G^{\text{pos}}$, $\hat{\mu} \in \hat{\Lambda}_G$, cf. [BFGM02, §1.5, p. 7]. Define the substack $\overline{\text{Bun}}_B^{\hat{\mu}}$ to be the image of the corresponding embedding. We obtain an open substack $\overline{\text{Bun}}_B^{\hat{\nu}, \hat{\mu}} \subset \overline{\text{Bun}}_B^{\hat{\mu}}$ by taking the union of the strata $\overline{\text{Bun}}_B^{\hat{\mu}}$ for all $\hat{\nu}' \leq \hat{\nu}$.

Since $\overline{\mathcal{Y}}^{\hat{\lambda}}$ maps to $\overline{\text{Bun}}_B^{-\hat{\lambda}}$ for $\hat{\lambda} \in \mathfrak{c}_X$, by base change we have locally closed subschemes

$$\overline{\nu} \overline{\mathcal{Y}}^{\hat{\lambda}} := \overline{\mathcal{Y}}^{\hat{\lambda}} \times_{\overline{\text{Bun}}_B^{\hat{\lambda}}} \overline{\text{Bun}}_B^{-\hat{\lambda}} \hookrightarrow \overline{\mathcal{Y}}^{\hat{\lambda}}$$

and open subschemes $\overline{\nu} \overline{\mathcal{Y}}^{\hat{\lambda}} \hookrightarrow \overline{\mathcal{Y}}^{\hat{\lambda}}$ defined analogously. Observe that the identification $\overline{\mathcal{Y}}^{\hat{\lambda}} \cong C_{\hat{\nu}} \times \overline{\text{Bun}}_B^{-\hat{\nu}}$ induces an isomorphism

$$\overline{\nu} \overline{\mathcal{Y}}^{\hat{\lambda}} \cong C_{\hat{\nu}} \times \mathcal{M}_X^{\hat{\lambda}} \hookrightarrow \overline{\nu} \overline{\mathcal{Y}}^{\hat{\lambda}} \hookrightarrow \overline{\mathcal{Y}}^{\hat{\lambda}}$$

On the other hand, $\overline{\mathcal{Y}}^{\hat{\lambda}}$ also maps to $\mathcal{M}_X$, so we get a locally closed subscheme

$$\overline{\nu} \overline{\mathcal{Y}}^{\hat{\lambda}, \hat{\nu}} := \overline{\nu} \overline{\mathcal{Y}}^{\hat{\lambda}} \times \mathcal{M}_X^{\hat{\nu}} \hookrightarrow \overline{\nu} \overline{\mathcal{Y}}^{\hat{\lambda}} \hookrightarrow \overline{\mathcal{Y}}^{\hat{\lambda}}.$$
for $\hat{\Theta}$ any partition in $c_X$ (by Lemma 3.1.6). We deduce from (4.5) that there is an isomorphism

$$\varphi \bar{Y}^\lambda \hat{\Theta} \cong C_\delta \times Y_\lambda \cdot \hat{\Theta}.$$  

In particular, Proposition 3.6.1 implies that $\varphi \bar{Y}^\lambda \hat{\Theta}$ is smooth. In summary:

**Proposition 4.2.1.** The collection of locally closed subschemes $\varphi \bar{Y}^\lambda \hat{\Theta}$, ranging over all $\hat{\nu} \in \hat{\Lambda}^\text{pos}_C$ and partitions $\hat{\Theta} \in \text{Sym}^{\infty}(c_X - 0)$, forms a smooth stratification of $\bar{Y}^\lambda$.

Note that for fixed $\lambda$, many of these strata may be empty.

### 4.2.2. Changing the curve.

In this subsection we let $C$ be a smooth curve which is not necessarily proper and we define

$$A(C) = \text{Hom}(c_X^\nu, \text{Sym} C), \quad \bar{y}(C) = \text{Maps}_{\text{gen}}(C, X/B \supset \text{pt})$$

and $\bar{y}(C)$ the closure of $\bar{y}(C)$ in $\text{Maps}_{\text{gen}}(C, X \times^G C G N / T \supset \text{pt})$ to emphasize the curve being used. Similarly we have $A^\lambda(C)$, $\bar{y}^\lambda(C)$, $\bar{Y}^\lambda(C)$. The local nature of $\bar{y}(C)$ (in particular Lemma 4.1.2) ensures that $\bar{Y}^\lambda(C)$ is still a finite type $k$-scheme.

Let $p : \tilde{C} \to C$ be an étale map of smooth curves. Let $(\text{Sym} \tilde{C})_\text{disj} \subset \text{Sym} \tilde{C}$ be the open subset that consists of divisors $\tilde{D}$ on $\tilde{C}$ such that the divisor $p^*(p_* (\tilde{D})) - \tilde{D}$ is disjoint from $\tilde{D}$. Let $A(\tilde{C})_\text{disj}$ denote the open subset of $\text{Hom}(\Lambda^+_X, \text{Sym} \tilde{C})$ consisting of homomorphisms landing in $(\text{Sym} \tilde{C})_\text{disj}$. Then pushforward of divisors defines a map $A^\lambda(\tilde{C}) \to A^\lambda(C)$.

**Proposition 4.2.3 ([BFG06, Proposition 2.19]).** For an étale map $\tilde{C} \to C$ we have a canonical isomorphism

$$\bar{Y}^\lambda(C) \times_{A^\lambda(C)} A^\lambda(\tilde{C})_\text{disj} \cong \bar{Y}^\lambda(\tilde{C}) \times_{A^\lambda(\tilde{C})} A^\lambda(C)_\text{disj}$$

which preserves the fine stratification.

Note that setting $\tilde{C} = C \sqcup C$ recovers the graded factorization property.

**Proof.** Choose $\delta \in c_X^\nu$ as in §3.7.1. For $(y, \hat{\tilde{a}}) \in \bar{Y}^\lambda(C) \times_{A^\lambda(C)} A^\lambda(\tilde{C})_\text{disj}$, let $\tilde{D}$ (resp. $D$) denote the divisor corresponding to $\delta$ paired with $\hat{\tilde{a}}$ (resp. $\pi(y) \in A^\lambda(C)$). Then $p_* \tilde{D} = D$ and $p^* D - \tilde{D}$ is disjoint from $\tilde{D}$. We deduce that there is an isomorphism $\tilde{C}_D' \cong \tilde{C}'_D$. Lemma 3.7.7, applied to the affine $G \times T$-scheme $X \times G N$, implies that the point $y \in \bar{Y}^\lambda(C)$ is equivalent to its restriction $y|_{\tilde{C}_D'}$. Applying the same lemma again shows that $y|_{\tilde{C}_D'}$ is equivalent to a point $\tilde{y} \in \bar{Y}^\lambda(\tilde{C})$ such that $\tilde{y}(\tilde{C} - \tilde{D}) = \text{pt}$. This defines mutually inverse maps in both directions and the compatibility with strata is clear.

Since the diagonal $\delta^\lambda : \tilde{C} \hookrightarrow A^\lambda(\tilde{C})$ sending $\hat{\nu} \mapsto \lambda \cdot \hat{\nu}$ is contained in $A^\lambda(\tilde{C})_\text{disj}$, we deduce from the graded factorization property and Proposition 4.2.3 that $\bar{Y}^\lambda(C)$ is étale-locally isomorphic to $\bar{Y}^\lambda(A^\lambda)$ for any smooth curve $C$. 
4.3. The central fiber. Let \( \lambda \in \mathcal{C}_X \). There is a diagonal map \( \delta^\lambda : C \to A^\lambda \) sending \( v \mapsto \lambda \cdot v \). For a fixed point \( v \in |C| \), let us consider \( \delta^\lambda : v \to A^\lambda \).

Define the central fiber \( Y^\lambda \) of \( Y^\lambda \) to be the preimage of \( \delta^\lambda \) under \( \pi : Y^\lambda \to A^\lambda \). If we take central fibers of the map \((3.6)\), Proposition 3.7.2 implies that we have a closed embedding \( Y^\lambda \hookrightarrow Gr_B \). In fact, \( \lambda \cdot v \) can be considered as a point in \( Gr_T \). If we let \( Gr^\lambda_B \) denote the preimage of this point under the projection \( Gr_B \to Gr_T \), then \( Y^\lambda \subset Gr^\lambda_B \).

The connected component \( (Gr^\lambda_B)_{\text{red}} \) with the reduced scheme structure is locally closed in \( Gr_G \) (cf. [Zhu17, Proposition 5.3.6]). We denote the image by \( S^\lambda \subset Gr_G \), which may also be described as the LN-orbit of \( t^\lambda \) in \( Gr_G \). The orbits \( S^\lambda \) are commonly known as the semi-infinite orbits of \( Gr_G \), and their geometric properties were extensively studied by Mirković–Vilonen in [MV07]. To summarize, we have a closed embedding

\[
(4.6) \quad (Y^\lambda)_{\text{red}} \hookrightarrow S^\lambda.
\]

We analogously define \( \overline{Y}^\lambda \) as the central fiber of \( \overline{\pi} : \overline{Y}^\lambda \to \overline{A}^\lambda \), and we deduce from Lemma 4.1.2 that there is a closed embedding \( (\overline{Y}^\lambda)_{\text{red}} \hookrightarrow Gr_G \). The stratifications of \( \overline{Y}^\lambda \) and \( S^\lambda \) are both indexed by the \( \rho \in \hat{A}^G \) (see Proposition 3.4.1). Observe that \( \overline{Y}^\lambda \cap \overline{\rho}^\lambda \cong \{ \overline{\rho} \} \times \overline{Y}^{\rho} \) is sent to \( S^{\lambda - \rho} \subset S^\lambda \) under the previous embedding. We deduce that there is a closed embedding

\[
(4.7) \quad (\overline{Y}^\lambda)_{\text{red}} \hookrightarrow \overline{S}^\lambda.
\]

4.3.1. Local description of \( Y^\lambda \). Note that the central fiber \( Y^\lambda \) intersects the stratum \( Y^\lambda, \theta \) only if \( \Theta = \{ \theta \} \) is the singleton partition corresponding to a single \( \theta \in \mathcal{C}_X \) \( \setminus \{ \emptyset \} \). In this case, let \( Y^\lambda, \theta \) denote the intersection \( Y^\lambda \cap Y^\lambda, \theta = Y^\lambda \times_{M_X} M^\theta_X \). Also let \( \overline{Y}^\lambda, \theta = \overline{Y}^\lambda \times_{M_X} M^\theta_X \).

The \( LG \)-action on the base point \( x_0 \in LX(k) \) defines a map \( LG \to LX \), which induces a map \( Gr_G \to LX/L^+G \).

Lemma 4.3.2. There are natural isomorphisms

\[
(4.8) \quad Y^\lambda \cong Gr^\lambda_{LX/L^+G} \times L^+X/L^+G
\]

\[
(4.9) \quad (\overline{Y}^\lambda)_{\text{red}} \cong (\overline{S}^\lambda \times L^+X/L^+G)_{\text{red}}
\]

which induce \( (Y^\lambda, \theta)_{\text{red}} \cong S^\lambda \times L^+X/L^+G \) and \( (\overline{Y}^\lambda, \theta)_{\text{red}} \cong \overline{S}^\lambda \times L^+X/L^+G \).

Proof. Consider the composition \( Gr^\lambda_B \to Gr_G \to LX/L^+G \). It follows from the definitions that we have an embedding

\[
Y^\lambda \hookrightarrow Gr^\lambda_B \times L^+X/L^+G
\]

The map in the reverse direction is defined using Beauville–Laszlo’s theorem: for a \( k \)-algebra \( R \), an \( R \)-point of \( Gr^\lambda_B \) consists of a \( B \)-bundle \( \mathcal{P}_B \) on \( \text{Spec} R[t] \) and a section \( \sigma_0 : \text{Spec} R(\mathfrak{t}) \to \mathcal{P}_B \). Using the identification \( B \cong X^\circ \), we can identify \( \beta \) with a section \( \beta : \text{Spec} R(\mathfrak{t}) \to X^\circ \times B \mathcal{P}_B \). If the image of \( (B_F, \beta) \) \( \in LX/L^+G \) belongs to \( L^+X/L^+G \), then \( \beta \) extends to a section \( \text{Spec} R[\mathfrak{t}] \to \mathcal{P}_B \).

\[15\] The open subscheme \( Y^\lambda \) does not need to be dense in \( \overline{Y}^\lambda \).
where the latter is a closed sub-ind-scheme of $Y^4$. Example 4.3.3 implies that the central fibers of $\bar{\mathfrak{X}}^\lambda$. Given an irreducible component $X \times B \mathfrak{p}_B$. By Lemma 3.7.7, the pair $(\mathfrak{p}_B, \sigma)$ is equivalent to an $R$-point $y \in Y$. By construction, $y \in Y^\lambda$. The two maps are mutually inverse, so we get (4.8).

For the second isomorphism, (4.7) gives a closed embedding 

$$(\nabla^\lambda)_{\text{red}} \hookrightarrow \mathfrak{S}^\lambda_{XY/L^+G}$$

where the latter is a closed sub-ind-scheme of $\mathfrak{S}^\lambda$. Since $\mathfrak{S}^\lambda = \bigcup_{\nu \geq 0} \mathfrak{S}^{\lambda-\nu}$, we deduce from (4.8) that $\mathfrak{S}^{\lambda-\nu}_{XY/L^+G} \times_{L^+X/L^+G} G$ is nonempty for only finitely many $\nu$. Moreover, because $\mathfrak{Y}^{\lambda-\nu}$ is of finite type, we further deduce that $\mathfrak{S}^{\lambda}_{XY/L^+G} L^+X/L^+G$ is a $k$-scheme of finite type. Now (4.9) may be checked as a bijection on $k$-points, which follows from the previous discussion.

The other identifications are by definition.

We included the subscript $\text{red}$ above for clarity, but from now on we consider only the underlying reduced structure on all central fibers and omit the subscript since the étale site is insensitive to reduced structures.

Example 4.3.3. Resume the setting of Example 3.3.1. Then $Y^{n_1 \mathfrak{p}_D^+ + n_2 \mathfrak{p}_D^-}$ is empty if both $n_1$ and $n_2$ are nonzero. Otherwise it consists of a single point. If we use the embedding $G_m \to GL_2$ via $a \mapsto \begin{pmatrix} 1 & a \\ \frac{1}{a} & 0 \end{pmatrix}$ and fix the base point $x_0 = 1$, then $Y^{\mathfrak{p}_D^+}$ corresponds to the point $(\frac{1}{a}, \frac{1}{a}) \mathfrak{t} \in Gr_B$ while $Y^{\mathfrak{p}_D^-}$ corresponds to $t^{-\mathfrak{f}} \in Gr_B$.

4.3.4. Lemma 4.3.2 implies that the central fibers $\mathfrak{Y}^\lambda, \nabla^\lambda$ can be defined purely locally (in particular, independent of the point $v \in |C|$). We also deduce that $\mathfrak{Y}^\lambda \times_{\mathfrak{A}^\lambda, \delta^\lambda} C \cong \mathfrak{Y}^\lambda \times C$ and $\nabla^\lambda \times_{\mathfrak{A}^\lambda, \delta^\lambda} C \cong \nabla^\lambda \times_{\mathfrak{A}^\lambda, \delta^\lambda} C$, where $? \times C := ? \times \text{Aut}_k[t[t] C^\wedge$ and $C^\wedge \to C$ is the $\text{Aut}_k[t[t]$-torsor classifying $v \in C$ together with an isomorphism $\phi \cong k[t[t]$. 4.4. Dimension of central fibers. We will now discuss an argument that is critical when estimating dimensions of Zastava spaces and their central fibers. This argument appeared in the proof of [MV07, Theorem 3.2]. The second author thanks M. Finkelberg for explaining this proof to him.

Semi-infinite orbits have a very simple geometric structure, summarized by the following:

Proposition 4.4.1 ([MV07, Proposition 3.1]). We have

(i) $\mathfrak{S}^\lambda = \bigcup_{\lambda \leq \lambda} \mathfrak{S}^{\lambda^\vee}$.

(ii) Inside $\mathfrak{S}^\lambda$, the boundary of $\mathfrak{S}^\lambda$ is given by a hyperplane section under an embedding of $Gr_G$ in projective space.

In particular, if a projective subvariety meets the semi-infinite orbit $\mathfrak{S}^\lambda$, it also meets its boundary $\bigcup_{\lambda^\vee} \mathfrak{S}^{\lambda^\vee}$. We will use this simple fact several times, in order to estimate the dimensions of central fibers.

For $\lambda \in c_X$, consider the central fiber $\nabla^\lambda \subset \mathfrak{S}^\lambda \subset Gr_G$. Observe that the defect stratification of $\nabla^\lambda$ gives a stratification of $\nabla^\lambda = \bigcup_{\lambda \leq \lambda} \mathfrak{Y}^{\lambda^\vee}$, where $\mathfrak{Y}^{\lambda^\vee} = \nabla^\lambda \cap \nabla^{\lambda^\vee}$. This is compatible with the stratification of $\mathfrak{S}^\lambda = \bigcup_{\lambda \leq \lambda} \mathfrak{S}^{\lambda^\vee}$ under the closed embedding $\nabla^\lambda \subset \mathfrak{S}^\lambda$. From Lemma 4.3.2 we have $\nabla^\lambda \cap \mathfrak{S}^{\lambda^\vee} = \mathfrak{Y}^{\lambda^\vee}$ for $\lambda \leq \lambda^\vee$.

Proposition 4.4.2. Given an irreducible component $\nabla \subset \mathfrak{S}^\lambda$ of the central fiber $\nabla^\lambda$ of $\nabla^\lambda$, there is a $\lambda^\vee \leq \lambda$ with $\nabla \cap \mathfrak{S}^{\lambda^\vee}$ nonempty of dimension zero, and $d := \dim \nabla \leq \langle \rho_G, \hat{\lambda} - \lambda \rangle$. Moreover,
if this inequality is an equality, there is a sequence of simple roots $\alpha_1, \ldots, \alpha_d$ (possibly with repetitions) such that $\dim(\overline{\mathcal{Y}} \cap S^{\lambda - \alpha_1 - \ldots - \alpha_j}) = d - j$.

**Proof.** By the stratification $S^\lambda = \bigcup_{\lambda_0 \leq \lambda} S^{\lambda_0}$, there must exist $\lambda_0 \leq \lambda$ such that $\mathcal{Y}_0 \cap S^{\lambda_0}$ is dense in $\overline{\mathcal{Y}}$. Then $\overline{\mathcal{Y}} \subset S^{\lambda_0}$ so we may assume $\lambda = \lambda_0$. Write $\partial S^\lambda = S^\lambda - S^\lambda$ for the hyperplane of Proposition 4.4.1(ii). Since $\overline{\mathcal{Y}}$ is a projective subvariety of $S^\lambda$, it must meet $\partial S^\lambda$. Hence there exists $\lambda_1 < \lambda$ such that $\dim(\overline{\mathcal{Y}} \cap S^{\lambda_1}) = d - 1$. Let $\mathcal{Y}_1$ be any irreducible component of $\overline{\mathcal{Y}} \cap S^{\lambda_1}$ and $\mathcal{Y}_1$ its closure in $S^{\lambda_1}$. Continuing in this fashion we produce a sequence of coweights $\lambda_j$, $i = 0, \ldots, d$, such that $\lambda_j < \lambda_{j-1}$ and $\dim(\overline{\mathcal{Y}} \cap S^{\lambda_j}) = d - j$. Since $\lambda_j < \lambda_{j-1}$ implies $\langle \rho_G, \lambda_j - \lambda_{j-1} \rangle \geq 1$, we get $\langle \rho_G, \lambda - \lambda_d \rangle \geq d$ and $\lambda' = \lambda_d$ is the claimed coweight in the proposition statement. In order for the last inequality to be an equality, we must have $\lambda = \lambda_0$ and $\lambda_j = \lambda_j - \alpha_j$ for some simple coroot $\alpha_j$, $j = 1, \ldots, d$. \hfill $\Box$

### 4.5. Comparison of IC complexes.

In order to describe the restriction of IC on to strata we will need to introduce several (graded) factorization algebras on the collection of $C_{\bar{\nu}}$, $\bar{\nu} \in \Lambda^\text{pos}_{G^\text{aff}}$. We only state their definitions; we refer the reader to [BG08, Gai] for further context.

Let $\mathfrak{n}_C = \mathfrak{n} \otimes \bigoplus_{\ell} \mathfrak{g}_\ell$ be the constant sheaf of Lie algebras over $C$. Let $\mathcal{U}(\mathfrak{n}_C)^\phi$ denote the following sheaf on $C_0$ for $\nu \in \Lambda^\text{pos}_{G^\text{aff}}$: its fiber at a point $\sum \nu_i \cdot v_i$ with $v_i \in [C]$ distinct is the tensor product $\bigotimes_i \mathcal{U}(\mathfrak{g})^{v_i}$ where the superscript $v_i$ refers to the corresponding weight space of the universal enveloping algebra $\mathcal{U}(\mathfrak{g})$. These fibers glue to a sheaf by means of the co-multiplication map on $\mathcal{U}(\mathfrak{n})$. Let $\mathcal{U}^{\nu}(\mathfrak{n}_C)^{-\nu} = \mathcal{D}(\mathcal{U}(\mathfrak{n}_C)^{\phi}) \in D^b(C_0)$ denote the Verdier dual.

We will also need the Chevalley–Cousin complex $\mathcal{Y}(\mathfrak{n}_C)$ of $\mathfrak{n}_C$. Consider the (homological) Chevalley complex $C_\bullet(\mathfrak{n}_C)$ as a sheaf of co-commutative DG co-algebras on $C$, endowed with a grading by elements of $\Lambda^\text{pos}_{G^\text{aff}}$. By the general procedure of [BD04, §3.4], a sheaf of $\Lambda^\text{pos}_{G^\text{aff}}$-graded co-commutative DG co-algebras on $C$ is equivalent to a co-commutative factorization algebra on $\mathcal{Y}$. We let $\mathcal{Y}(\mathfrak{n}_C)^\phi$ denote the corresponding complex on $C_0$, which can be explicitly constructed via a Cousin complex. Its fiber at $\sum \nu_i \cdot v_i$ with $v_i$ distinct is the tensor product $\bigotimes_i C_\bullet(\mathfrak{n}_C)^{v_i}$. We remark that $\mathcal{Y}(\mathfrak{n}_C)^\phi$ is actually a perverse sheaf, and $\mathcal{Y}(\mathfrak{n}_C)$ and $\mathcal{U}^{\nu}(\mathfrak{n}_C)$ are related by a certain Koszul duality.

#### 4.5.1. Let

$$i_{\mathcal{Y}, \nu}: C_{\bar{\nu}} \times Y^{\lambda - \nu} \hookrightarrow Y^\lambda$$

denote the locally closed embedding corresponding to (4.5).

**Proposition 4.5.2.** For any $\lambda \in c_X$, $\nu \in \Lambda^\text{pos}_{G^\text{aff}}$, there is an equality

$$[i^*_{\mathcal{Y}, \nu}](\text{IC}_{Y^\nu}) = [\mathcal{U}^{\nu}(\mathfrak{n}_C)^{-\nu} \boxtimes \text{IC}_{Y^{\lambda - \nu}}]$$

in the Grothendieck group of perverse sheaves on $C_{\bar{\nu}} \times Y^{\lambda - \nu}$.

Given a map $f: Y \to S$ between finite type algebraic $k$-stacks, we use the notion of a complex on $Y$ which is *universally locally acyclic* (ULA) with respect to $f$, as in [Del77, Définition 2.12]. We refer the reader to Appendix B for a review of the ULA property.

The general lemma we will use is the following:
Lemma 4.5.3 ([BG02, Lemma 7.1.3]). Consider a Cartesian diagram of finite type algebraic stacks

\[
\begin{array}{ccc}
Y' & \xrightarrow{f'} & S' \\
\downarrow{g'} & & \downarrow{g} \\
Y & \xrightarrow{f} & S
\end{array}
\]

where \( S \) is smooth. Let \( j : Y_0 \hookrightarrow Y \) be an open dense substack such that the map \( f \circ j : Y_0 \to S \) is smooth. In addition, assume that the complexes \( IC_Y \) and \( j_!(IC_{Y_0}) \) are ULA with respect to the map \( f \).

Denote the closure\(^\text{16}\) of \( Y_0 \times_S S' \) in \( Y' \) by \( Y_0 \times_S S' \). Then there is a natural isomorphism

\[
IC_{Y_0 \times_S S'} \cong IC_S \boxtimes IC_Y := f'^*(IC_{S'}) \otimes g'^*(IC_Y)[− \dim S],
\]

where the left hand side is implicitly extended by zero to \( Y' \).

For completeness, we give a proof of Lemma 4.5.3 in Appendix B.

We would like to apply this lemma with \( Y = \text{Bun}_B, Y_0 = \text{Bun}_G, S = \text{Bun}_G, \) and \( S' = \mathcal{M}_X \). Unfortunately the stack \( \text{Bun}_B \) is “too big” for all of \( IC_{\text{Bun}_B} \) to be ULA over \( \text{Bun}_G \). However, we do get the ULA property if we restrict to open substacks where the defect is not “too big":

Let \( j : \text{Bun}_B \to \text{Bun}_B \) denote the open embedding.

Proposition 4.5.4 ([Cam19, Cam18]). Fix \( \check{\nu} \in \check{\Lambda}_G^{\text{pos}} \). Then for any \( \check{\mu} \in \check{\Lambda}_G \) large enough:

(i) The complexes \( IC_{\leq \check{\nu}}^{\text{Bun}_B^{\check{\mu}}} \) and \( j_!(IC_{\text{Bun}_B^{\check{\mu}}} \big|_{\leq \check{\nu}}^{\text{Bun}_B^{\check{\mu}}}) \) are ULA over \( \text{Bun}_G \).

(ii) The fiber of \( \text{Bun}_B^{\check{\mu}} \to \text{Bun}_G \) is dense in the fiber of \( \leq \check{\nu} \text{Bun}_B^{\check{\mu}} \to \text{Bun}_G \) over any \( k \)-point of \( \text{Bun}_G \).

Here “large enough” is in the same sense as in Lemma 3.5.1, i.e., deep enough in the dominant chamber \( \check{\Lambda}_G^+ \).

Proof. The ULA property for \( IC_{\leq \check{\nu}}^{\text{Bun}_B^{\check{\mu}}} \) is [Cam19, Corollary 4.1.1.1]. The ULA property for \( j_!(IC_{\text{Bun}_B^{\check{\mu}}} \big|_{\leq \check{\nu}}^{\text{Bun}_B^{\check{\mu}}}) \) can be deduced from the former, cf. [Cam18, §4.3]. We review the salient features of the proof in [Cam19] to deduce (ii).

The key object introduced in [Cam19] is Kontsevich’s compactification \( \overline{\text{Bun}}^K_B \) of \( \text{Bun}_B \), which is a resolution of singularities \( \overline{\text{Bun}}^K_B \to \overline{\text{Bun}}_B \) of Drinfeld’s compactification. For an affine test scheme \( S \), an \( S \)-point of \( \overline{\text{Bun}}^K_B \) is a commutative square

\[
\begin{array}{ccc}
\tilde{\mathcal{C}} & \xrightarrow{p_G} & \text{pt}/G \\
\downarrow & & \downarrow \\
C \times S & \xrightarrow{p_G} & \text{pt}/G
\end{array}
\]

where \( \tilde{\mathcal{C}} \to S \) is a flat family of connected nodal projective curves of the same arithmetic genus as \( C \), the map \( \tilde{\mathcal{C}} \to C \times S \) has degree 1, and the induced section \( \tilde{\mathcal{C}} \to \mathcal{P}_G \times^G S/B \) is stable in the sense of [Kon95] over every geometric point of \( S \). Let \( \mathcal{M}_C \) denote the moduli stack of proper connected nodal curves \( \tilde{\mathcal{C}} \) equipped with a degree one map to \( C \). Then the natural map \( \overline{\text{Bun}}^K_B \to \mathcal{M}_C \) is smooth, and \( \mathcal{M}_C \) is smooth ([Cam19, Proposition 2.4.1]) and there is a proper map \( \overline{\text{Bun}}^K_B \to \overline{\text{Bun}}_B \) over \( \text{Bun}_G \) ([Cam19, Proposition 3.2.2]). Inside \( \mathcal{M}_C \) we have the open point corresponding to \( \text{id} : C \to C \) and the complement \( \partial \mathcal{M}_C \) is a normal crossings divisor.

\(^{16}\)In general it is possible for \( Y' \) to have more irreducible components than \( Y_0 \times_S S' \).
Now for any \( \nu_p \in \text{Bun}_B \), denote the preimage of \( \nu_p \) in \( \text{Bun}_B \) by \( \nu_p \). Let \( \nu_p \) denote the preimage of \( \nu_p \). Then \( \nu_p \) shows that for \( \nu_p \) fixed and \( \nu_p \) large enough, the map \( \nu_p \) is smooth. Now for any \( \nu_p \in \text{Bun}_G(k) \), the fiber of \( \nu_p \) is smooth over \( \text{Bun}_G \). The preimage over the open point equals \( \nu_p \), and since \( \partial \mathcal{M} \) is a normal crossings divisor, \( \nu_p \) is dense in \( \nu_p \). Since \( \nu_p \) is dense in \( \nu_p \), we have proved (ii). \( \square \)

**Corollary 4.5.5.** For any \( \lambda \in \mathfrak{c}_X \), the subscheme \( \mathfrak{y}^\lambda \) is dense in \( \mathfrak{y}^\lambda \).

We will prove Proposition 4.5.2 and Corollary 4.5.5 together:

**Proof.** The subschemes \( \nu_p \) form an open covering of \( \mathfrak{y}^\lambda \). Since \( \mathfrak{y}^\lambda \) is quasi-compact, there must exist some \( \nu_p \) such that \( \nu_p \) is dense in \( \mathfrak{y}^\lambda \). Fix \( \lambda, \nu_p \) as above. Then we can choose \( \lambda, \nu_p \) such that \( \lambda, \nu_p \) is large enough, for all \( 0 \leq \nu_p \leq \nu_p \), for the purposes of Proposition 4.5.4 and Lemma 3.5.1. Now we may consider \( \nu_p \) as an open subscheme of \( \nu_p \). For any \( \nu_p \), \( \nu_p \) is dense in \( \nu_p \). The graded factorization property of \( \nu_p \) gives a natural étale map

\[
\nu_p \times \nu_p := (\nu_p \times \nu_p)|_{\nu_p \times \nu_p} \rightarrow \nu_p \times \nu_p,
\]

where \( \nu_p \) is the open embedding. We deduce that \( \nu_p \times \nu_p \) is dense in \( \nu_p \times \nu_p \), which implies \( \nu_p \) is dense in \( \nu_p \).

Applying Lemma 4.5.3 to the Cartesian square

\[
\begin{array}{ccc}
\nu_p \times \nu_p & \rightarrow & \nu_p \times \nu_p \\
\downarrow & & \downarrow \\
\text{Bun}_G \rightarrow \text{Bun}_G
\end{array}
\]

we can identify

\[
\text{IC}_{\nu_p} \cong \text{IC}_{\nu_p} \otimes \text{IC}_{\nu_p} \otimes \nu_p \text{Bun}_G.
\]

In particular, this gives us a description of \( \text{IC}_{\nu_p} \cong \text{IC}_{\nu_p} \) for \( 0 \leq \nu_p \leq \nu_p \). For \( 0 \leq \nu_p \leq \nu_p \), we have a Cartesian square

\[
\begin{array}{ccc}
\nu_p \times \nu_p & \rightarrow & \nu_p \times \nu_p \\
\downarrow & & \downarrow \\
\text{Bun}_G \rightarrow \text{Bun}_G
\end{array}
\]

**Lemma 4.5.6 ([BG08, Proposition 4.4], [BFGM02, Theorem 1.12]).** There exists a canonical isomorphism

\[

\text{IC}_{\nu_p} \cong \nu_p \otimes \nu_p \text{Bun}_G
\]

for any \( \nu_p \in \mathfrak{c}_X \), \( \nu_p \in \mathfrak{c}_X \).
This lemma together with the Cartesian square above and (4.11) allows us to deduce that there exists an isomorphism
\[
i_{Y^\nu, \rho}(IC_{Y^{\lambda+\mu}}) \cong \mathcal{V}^\nu(\hat{n}_C)^{-\rho} \boxtimes (IC_{\mathcal{M}_X} \boxtimes IC_{\text{Bun}_G})|_{y^{\lambda+\mu-\nu}} = \mathcal{V}^\nu(\hat{n}_C)^{-\rho} \boxtimes (IC_{\mathcal{M}_X}|_{y^{\lambda+\mu-\nu}})
\]
on $C^\nu \times y^{\lambda+\mu-\nu}$. In the last equality we have used the fact that $\text{Bun}_G$ is smooth. Since we chose $\lambda + \mu - \nu$ large enough to satisfy Lemma 3.5.1, the map $y^{\lambda+\mu-\nu} \to \mathcal{M}_X$ is smooth. Therefore $IC_{\mathcal{M}_X}|_{y^{\lambda+\mu-\nu}} \cong IC_{y^{\lambda+\mu-\nu}}$ and we get a canonical isomorphism
\[
(4.12) \quad i_{Y^\nu, \rho}(IC_{Y^{\lambda+\mu}}) \cong \mathcal{V}^\nu(\hat{n}_C)^{-\rho} \boxtimes IC_{Y^{\lambda+\mu-\nu}}.
\]
Observe that the following diagram is Cartesian:
\[
\begin{array}{ccc}
(C^\nu \times y^{\lambda-\nu}) \times y^{\mu} & \xrightarrow{\iota_{Y^\nu, \rho} \times \text{id}} & (\mathcal{V}^\nu(\hat{n}_C)^{-\rho} \boxtimes IC_{\mathcal{M}_X})|_{y^{\lambda+\mu-\nu}} \\
\downarrow & & \downarrow |_{(\mathcal{V}^\nu(\hat{n}_C)^{-\rho} \boxtimes IC_{\mathcal{M}_X})|_{y^{\lambda+\mu-\nu}}} \\
C^\nu \times y^{\lambda+\mu-\nu} & \xrightarrow{\iota_{Y^\nu, \rho}} & y^{\lambda+\mu}
\end{array}
\]
where the left vertical arrow is identity on $C^\nu$ times the map $y^{\lambda-\nu} \times y^{\mu} \to y^{\lambda+\mu-\nu}$ coming from graded factorization. Since the restriction of $IC_{Y^{\lambda+\mu}}$ to $\overline{y}^{\lambda} \times y^{\mu}$ is $IC_{\mathcal{M}_X} \boxtimes IC_{y^\mu}$, we deduce from the Cartesian square and (4.12) that there is a canonical isomorphism
\[
i_{Y^\nu, \rho}(IC_{Y^{\lambda+\mu}}) \boxtimes IC_{y^\mu} \cong (\mathcal{V}^\nu(\hat{n}_C)^{-\rho} \boxtimes IC_{\mathcal{M}_X}) \boxtimes IC_{y^\mu},
\]
when restricted to $(C^\nu \times y^{\lambda-\nu}) \times y^{\mu}$. Lastly, let $\mathcal{Y}$ be a connected component of $y^{\mu, 0}$ so that the projection $p : (C^\nu \times y^{\lambda-\nu}) \times \mathcal{Y} \to C^\nu \times y^{\nu-\nu}$ is smooth with irreducible fibers. We have constructed an isomorphism
\[
p^*(i_{Y^\nu, \rho}(IC_{Y^{\lambda+\mu}})) \cong p^*(\mathcal{V}^\nu(\hat{n}_C)^{-\rho} \boxtimes IC_{\mathcal{M}_X}),
\]
which implies Proposition 4.5.2 because the functor $p^*|_{\dim \mathcal{Y}}$ is fully faithful on the category of perverse sheaves ([BBDG18, Proposition 4.2.5]).}

We have a closed embedding $i_{\mathcal{A}^\rho, \rho} : C^\nu \hookrightarrow \mathcal{A}^\rho$ corresponding to the partition $\sum_i n_i [\hat{\alpha}_i]$ of degree $\nu = \sum_i n_i \hat{\alpha}_i$.

**Corollary 4.5.7.** There is an equality
\[
[p(\text{IC}_{\mathcal{Y}^\lambda})] = \sum_{\nu \in \Lambda_G^{\text{pos}}} [i_{\mathcal{A}, \nu}(\mathcal{Y}(\hat{n}_C)^\nu) \star \hat{p}(\text{IC}_{\mathcal{Y}^{\lambda+\nu}})]
\]
in the Grothendieck group of perverse sheaves on $A^\lambda$.

**Proof.** Taking the Grothendieck–Cousin complex associated to the stratifications $i_{Y^\nu, \rho}$ and applying Proposition 4.5.2 gives an equality
\[
[\text{IC}_{\mathcal{Y}^\lambda}] = \sum_{\nu \in \Lambda_G^{\text{pos}}} [i_{Y^\nu, \rho}(\mathcal{V}^\nu(\hat{n}_C)^{-\rho} \boxtimes IC_{Y^{\lambda-\nu}})]
\]
in the Grothendieck group of perverse sheaves on $\mathcal{Y}^\lambda$. Note that $y^{\lambda-\nu}$ is nonempty for finitely many values of $\nu$. The composition $\hat{p} \circ i_{Y^\nu, \rho} : C^\nu \times y^{\lambda-\nu} \to \mathcal{A}^\lambda$ coincides with the composition...
$C_{\tilde{\nu}} \times Y^{\tilde{\lambda} - \tilde{\nu}} \xrightarrow{i_{\tilde{\lambda}, \tilde{\nu}, \pi}} A^{\tilde{\nu}} \times A^{\tilde{\lambda} - \tilde{\nu}} \rightarrow A^{\tilde{\lambda}}$. Therefore applying $\tilde{\pi}_1$ to the above equality, we get the equality

$$[\tilde{\pi}_1(\text{IC}_{\tilde{T}^{\tilde{\lambda}}})] = \sum_{\tilde{\nu} \in \Lambda_{G}^{\text{pos}}} [i_{\tilde{A}, \tilde{\nu}, !}(\text{IC}^\nu(\tilde{\mathcal{C}}_C))^\tilde{\nu}] \ast \pi_1(\text{IC}_{\tilde{\lambda} - \tilde{\nu}})$$

in the Grothendieck group of perverse sheaves on $A^{\tilde{\lambda}}$. Applying a further convolution by any $\mathcal{F} \in D^b_c(C_{\tilde{\nu}'}, \tilde{\nu}') \in \Lambda_{G}^{\text{pos}}$ gives

$$[i_{\tilde{A}, \tilde{\nu}', !}(\mathcal{F}) \ast \tilde{\pi}_1(\text{IC}_{\tilde{T}^{\tilde{\lambda}}})] = \sum_{\tilde{\nu}} [i_{\tilde{A}, \tilde{\nu} + \tilde{\nu}', !}(\mathcal{F} \ast \text{IC}^\nu(\tilde{\mathcal{C}}_C)^{\tilde{\nu}}) \ast \pi_1(\text{IC}_{\tilde{\lambda} - \tilde{\nu}})].$$

It is known ([BG08, §6.4]) that for a fixed nonzero $\tilde{\nu} \in \Lambda_{G}^{\text{pos}}$, we have an equality

$$\sum_{\tilde{\nu}_1, \tilde{\nu}_2 \in \Lambda_{G}^{\text{pos}}} [\mathcal{F}(\tilde{\mathcal{C}}_C)^{\tilde{\nu}_1} \ast \text{IC}^\nu(\tilde{\mathcal{C}}_C)^{-\tilde{\nu}_2}] = 0$$

in the Grothendieck group of perverse sheaves on $C_{\tilde{\nu}}$. The two preceding equalities and induction proves the claim.

5. Global Hecke action and closure relations

For the rest of this paper, assume that $\tilde{G}_X = \tilde{G}$ and all the spherical roots are of type $T$. Equivalently, we are assuming that $B$ acts simply transitively on $X^0$ and for every simple root $\alpha$ of $G$, the PGL$_2$-variety $X^0 P_\alpha / \mathcal{R}(P_\alpha)$ is isomorphic to $\mathbb{G}_m \setminus \text{PGL}_2$ (over the algebraically closed field $k$).

As a consequence, $\mathcal{V} \cap \Lambda_X = \Lambda_X^{\text{c}}$, the monoid of antidominant coweights of $G$. Recall from §2.1.1 that the type $T$ assumption also implies that for every simple root $\alpha$, the open $P_\alpha$-orbit $X^0 P_\alpha$ is the union of $X^0$ and the open $B$-orbits of two colors $\mathcal{D}(\alpha) = \{D^+_{\alpha}, D^-_{\alpha}\}$. We will let $\tilde{\nu}_\alpha^\pm$ denote the valuation of $D^+_{\alpha}$, respectively. Then $\tilde{\nu}_\alpha^+ + \tilde{\nu}_\alpha^- = \tilde{\alpha}$ and $\langle \alpha, \tilde{\nu}_\alpha^\pm \rangle = 1$.

5.1. Main results of this section. This section is quite technical, and we advise the reader to read the main results listed here, and skip the rest of the section at first reading. Before we introduce the results, let us observe that, so far, we have uniformly treated all affine spherical varieties. However, the classification of spherical varieties is divided into two parts: (i) the classification of homogeneous spherical varieties $H \setminus G$, and (ii) the classification of spherical embeddings $H \setminus G \hookrightarrow X$ (by a spherical embedding we mean a $G$-equivariant open, dense embedding $H \setminus G \hookrightarrow X$, where $X$ is a normal, and hence spherical, $G$-variety).

Since $X$ is affine, $X^\bullet = H \setminus G$ is quasi-affine and there is a canonical affine embedding

$$X^\text{can} := \text{Spec } k[H \setminus G].$$

(The fact that the coordinate ring of $k[H \setminus G]$ is finitely generated follows from the fact that $B$-eigenspaces are one-dimensional, and the $B$-character group is finitely generated.) By normality, $X^\text{can}$ has no divisors that do not meet $H \setminus G$, i.e., $\mathcal{D}(X)$ has no $G$-stable divisors, and coincides with the set $\mathcal{D}$ of colors. Therefore, the cone $\mathcal{C}_0(H \setminus G) := \mathcal{C}_0(X^\text{can})$ is generated by the valuations $\varrho_X(D)$ of colors.

For any other affine spherical embedding $H \setminus G \hookrightarrow X$, there is a natural map $X^\text{can} \to X$, so $X^\text{can}$ is universal among affine embeddings of $H \setminus G$.

It turns out that this distinction between the minimal and the general embeddings is important when we consider arc spaces and their global models. As we will recall in Lemma 5.6.5, the map $X^\text{can} \to X$ induces a closed embedding of mapping stacks

$$M_{X^\text{can}} \hookrightarrow M_X,$$
whose image is a union of irreducible components.

We are more interested in the closure of $M^0_{\mathcal{X}} = \text{Bun}_H$ in the former, which we will denote by $\overline{M^0_{\mathcal{X}}}$ (it may or may not be the same as $M_{\mathcal{X}^{\text{can}}}$ depending on whether the monoid $\mathcal{X}^{\text{can}}$ is generated by colors, see Corollary 5.6.3):

\begin{equation}
\overline{M^0_{\mathcal{X}}} \hookrightarrow M_{\mathcal{X}^{\text{can}}} \hookrightarrow M_{\mathcal{X}}.
\end{equation}

The main theme of this section is, in some sense, a reconstruction of $M_{\mathcal{X}}$ out of suitable Hecke operators acting on $\overline{M^0_{\mathcal{X}}}$: For any $\hat{\Theta} \in \text{Sym}^\infty(\mathcal{X}^{-0})$, a multiset of nonzero elements in $\mathcal{X}^{-0}$, there is a natural proper map

\begin{equation}
\text{act}_M : \overline{M^0_{\mathcal{X}}} \times \mathcal{G}_{\mathcal{X},C}^\Theta \rightarrow M_{\mathcal{X}},
\end{equation}

which corresponds to the action on the “basic stratum” $\overline{M^0_{\mathcal{X}}}$ of the closed stratum of the affine Grassmannian parametrized by $\hat{\Theta}$. (See Proposition–Construction 5.2.3.) Recall that such a multiset $\hat{\Theta}$ also parametrizes a stratum $M^\hat{\Theta}_{\mathcal{X}}$ of the global mapping space (§3.1.5). The main technical result of this section is the following:

**Theorem 5.1.1.** For every $\hat{\Theta} \in \text{Sym}^\infty(\mathcal{X}^{-0})$, the action map (5.2)

(i) has image equal to the closure of $M^\hat{\Theta}_{\mathcal{X}}$, and

(ii) is birational onto its image.

The proof of Theorem 5.1.1 will be given in §5.5.

We use this theorem to achieve two goals in this section:

1. **The first goal** is to understand irreducible components of $M_{\mathcal{X}}$ and closure relations among the strata $M^\hat{\Theta}_{\mathcal{X}}$. We will introduce the natural generalization to multisets of the order $\succeq$ among elements of the lattice $\hat{\Lambda}_{\mathcal{X}}$ (we remind that this order is determined by the monoid of colors, see §2.1), and prove:

**Proposition 5.1.2** (See Proposition 5.6.1). Let $\hat{\Theta}, \hat{\Theta}' \in \text{Sym}^\infty(\mathcal{X}^{-0})$. The stratum $M^{\hat{\Theta}'}_{\mathcal{X}}$ lies in the closure of $M^{\hat{\Theta}}_{\mathcal{X}}$ if and only if there exists $\hat{\Theta}''$ such that $\hat{\Theta}$ refines $\hat{\Theta}''$ and $\hat{\Theta}' \succeq \hat{\Theta}''$.

Moreover, observe that the irreducible components of $\overline{M^0_{\mathcal{X}}}$ are in bijection with connected components of $M_{\mathcal{X}}$, i.e., parametrized by $\pi_0(\text{Bun}_H) = \pi_1(H)$. Using the action (5.2) on that component gives us a parametrization of the irreducible components of the closure of each stratum:

**Proposition 5.1.3** (See Corollaries 5.5.9 and 5.7.2). For every $\hat{\Theta} \in \text{Sym}^\infty(\mathcal{X}^{-0})$, the irreducible components in the closure $\overline{M^0_{\mathcal{X}}}$ of the corresponding stratum are naturally parametrized by $\pi_1(H)$. For any $\hat{\lambda} \in \mathcal{X}$, the base change of an irreducible component to $Y^{\hat{\lambda}} \times M_{\mathcal{X}} \overline{M^0_{\mathcal{X}}}$ is still irreducible (when nonempty).

The combination of Propositions 5.1.2 and 5.1.3 implies:

**Corollary 5.1.4** (See Corollary 5.6.4). There is a natural bijection between the set of irreducible components of $M_{\mathcal{X}}$ and

$$\pi_1(H) \times \text{Sym}^\infty(D_{\text{sat}}(X)),$$

where $D_{\text{sat}}(X)$ denotes the set of primitive elements in $\mathcal{X}$ that cannot be decomposed as a sum $\theta + \nu_D$ where $\theta \in \mathcal{X}^{-0}$ and $\nu_D$ is the valuation attached to a color.

The second goal achieved by Theorem 5.1.1 is to reduce the study of the IC complex of an arbitrary mapping space $M_{\mathcal{X}}$ to that of the minimal affine embedding:
Theorem 5.1.5. For any $\tilde{\Theta} \in \text{Sym}^{\infty}(\tilde{c}_X - 0)$, there is a natural isomorphism

$$IC_{\Sigma X} \star IC_{\Sigma G,C,\tilde{\Theta}} \cong IC_{\Sigma X}. $$

We point to §5.8 for the notation and the proof. Theorem 5.1.5 and its proof are independent from the rest of this paper; we include it only for conceptual completeness. The proof involves a passage to Zastava model (the extra structure of a flag) and the ensuing analysis is in some ways analogous to that of [BG02, Theorem 3.1.4]. The argument of proof can also be extended to meromorphic quasimaps to verify [GN10, Conjecture 7.3.2] in the case $\hat{G}_X = \hat{G}$.

5.2. Hecke action on global model. Now we introduce the action map (5.2), as an analog of the action of $G(F)$ on $X^*(F)$ for the global model.

The notation is cumbersome because we give a multi-point version of the action, but the idea is simple: in the notation of §3.1.3, the $k$-points of $\mathcal{M}_X$ correspond to a subset of $H(k) \backslash G(\mathbb{A})/G(\mathbb{O})$, where $\mathbb{O} = \prod_{v \in |C|} \mathbb{O}_v$.

We have a Hecke correspondence

$$H(k) \backslash G(\mathbb{A}) \times G(\mathbb{A})/G(\mathbb{O}) \to H(k) \backslash G(\mathbb{A})/G(\mathbb{O})$$

induced by multiplication in $G$. We think of $G(\mathbb{A})/G(\mathbb{O})$ as a factorizable version of the affine Grassmannian. Then the “action map” is simply the restriction of the above to a positively graded subset of $G(\mathbb{A})/G(\mathbb{O})$ such that everything maps to $(X^*(\mathbb{A}) \cap X(\mathbb{O}))/G(\mathbb{O})$, i.e., the locus of regular maps.

5.2.1. Positively graded subscheme of factorizable affine Grassmannian. Let $\tilde{\Theta} = \sum_{\tilde{\theta}} N_{\tilde{\theta}}[\tilde{\theta}] \in \text{Sym}^{\infty}(\tilde{c}_X - 0)$ be a partition. We have a closed subscheme $\text{Gr}^{\tilde{\Theta}}_{G,C} = \tilde{\text{Gr}}^{\tilde{\Theta}_{G,C}} \subset \text{Gr}^{G}_{G,C}$ (see §A.1.1 for meaning of $\tilde{\times}$). Consider the $N_{\tilde{\theta}}$-fold product $\left(\tilde{\text{Gr}}^{\tilde{\Theta}_{G,C}}\right)^{N_{\tilde{\theta}}} \times C^{N_{\tilde{\theta}}}$ restricted to the disjoint locus with all diagonals removed. This descends to a subscheme $\tilde{\text{Gr}}^{\tilde{\Theta}_{G,C}} \subset \text{Gr}^{G,C}_{G,C}$.

In the notation of §3.1.4, let

$$\tilde{\text{Gr}}^{\tilde{\Theta}_{G,C}} := \left(\prod_{\tilde{\theta}} \tilde{\text{Gr}}^{N_{\tilde{\theta}}}_{G,C(\tilde{\Theta}_{\tilde{\theta}})} \right) \subset \text{Gr}^{G,C(\tilde{\Theta}_{\tilde{\theta}}}_{G,C(\tilde{\Theta}_{\tilde{\theta}})} \times C^{\tilde{\Theta}_{\tilde{\theta}}}$$

and let $\tilde{\text{Gr}}^{\tilde{\Theta}_{G,C}}$ denote its closure in $\text{Gr}^{G,C(\tilde{\Theta}_{\tilde{\theta}}}_{G,C(\tilde{\Theta}_{\tilde{\theta}})} \times C^{\tilde{\Theta}_{\tilde{\theta}}}$. We consider $\tilde{\text{Gr}}^{\tilde{\Theta}_{G,C}}$ as a scheme over $C^{\tilde{\Theta}_{\tilde{\theta}}}$ with an action of the group scheme $(\mathcal{L}^{G})_{C^{\tilde{\Theta}_{\tilde{\theta}}}}$, the multi-point version of the arc space defined in §A.1.

The closure relations of the Beilinson–Drinfeld affine Grassmannian are known (cf. [Zhu17, Proposition 3.1.14]), so we can describe the reduced fiber of $\tilde{\text{Gr}}^{\tilde{\Theta}_{G,C}}$ over a point of $C^{\tilde{\Theta}_{\tilde{\theta}}}$ as follows: a point of $C^{\tilde{\Theta}_{\tilde{\theta}}}$ is the collection $(D^\tilde{\theta})_{\tilde{\theta}}$, for each $\tilde{\theta}$, of a degree $N_{\tilde{\theta}}$ divisor $D^\tilde{\theta} = \sum_{v \in |C|} N_{\tilde{\theta},v} v$.

The reduced fiber of $\tilde{\text{Gr}}^{\tilde{\Theta}_{G,C}}$ over this point is the scheme

$$\prod_{v \in |C|} \text{Gr}^{\sum_{\tilde{\theta}} N_{\tilde{\theta},v} \tilde{\theta}}_{G,v}.$$  

5.2.2. Let $\hat{\mathcal{M}}_X$ denote the stack representing the data of

$$(\sigma, \mathcal{P}_G) \in \mathcal{M}_X, \ D \in \text{Sym} C,$$ and a trivialization $\mathcal{P}_G|_{\mathcal{L}_D} \cong \mathcal{P}_G|_{\mathcal{L}_D}$$

...
(see §3.7.5 for the definition of $\tilde{\mathcal{C}}_D^0$), i.e., a point of $\mathcal{M}_X$ together with infinite $G$-level structure at points in the support of $D$. This admits a natural action by $\mathcal{L}^+G$, and the forgetful map $\tilde{\mathcal{M}}_X \to \mathcal{M}_X \times \text{Sym} \, C$ is a $\mathcal{L}^+G$-torsor. Let 

\[ \mathcal{M}_X \times \tilde{\text{Gr}}_{G,C^\Theta} := \tilde{\mathcal{M}}_X \times_{\text{Sym} \, C} \tilde{\text{Gr}}_{G,C^\Theta} \]

denote the twisted product over $C(\langle \tilde{\Theta} \rangle) \subset \text{Sym} \, C$.

For an affine test scheme $S$, an $S$-point of $\mathcal{M}_X \times \tilde{\text{Gr}}_{G,C^\Theta}$ is the data $(\sigma, \mathcal{P}_G, \mathcal{P}'_G, (D^\Theta)_{\tilde{\theta}}, \tau)$ where 

- $\mathcal{P}_G, \mathcal{P}'_G$ are $G$-bundles on $C \times S$,
- $\sigma : C \times S \to X \times G P_G$ is a section such that $(\sigma, \mathcal{P}_G) \in \mathcal{M}_X(S)$,
- for each $\tilde{\theta} \in \mathcal{C}_X^\theta$, we have a degree $N_{\hat{\theta}}$ effective Cartier divisor $D_{\hat{\theta}} \subset C \times S$,
- $\tau : \mathcal{P}'_G|_{C \times S-D} \cong \mathcal{P}_G|_{C \times S-D}$ is a trivialization for $D := \sum_{\hat{\theta}} D_{\hat{\theta}}$

such that after fixing an isomorphism $\mathcal{P}_G|_{\tilde{C}_D^0} \cong \tilde{\mathcal{P}}_G|_{\tilde{C}_D^0}$ (which always exists after flat base change over $S$), the datum $((D^\Theta), \mathcal{P}'_G|_{\tilde{C}_D^0}, \tau)$ defines a point in $\tilde{\text{Gr}}_{G,C^\Theta}$. Here we are implicitly using Beauville–Laszlo’s theorem to pass between the global and local descriptions of $\text{Gr}_{G,\text{Sym} \, C}$, cf. §A.1.3.

**Proposition-Construction 5.2.3.** For any $\Theta \in \text{Sym}^\infty(\mathcal{C}_X^0)$ there is a natural proper map

\[ \text{act}_M : \mathcal{M}_X \times \tilde{\text{Gr}}_{G,C^\Theta} \to \mathcal{M}_X. \]

**Proof.** Fix an affine test scheme $S$ and $(\sigma, \mathcal{P}_G, \mathcal{P}'_G, (D^\Theta)_{\tilde{\theta}}, \tau) \in \mathcal{M}_X \times \tilde{\text{Gr}}_{G,C^\Theta}(S)$. The composition $\tau^{-1} \circ \sigma|_{C \times S-D}$ defines a section $\sigma' : C \times S-D \to X \times G \mathcal{P}'_G$. We claim that $\sigma'$ extends to a regular map on $C \times S$. Given this claim, we can define $(\sigma', \mathcal{P}'_G) \in \mathcal{M}_X(S)$ to be the image of $\text{act}_M$. Properness of $\text{act}_M$ follows from properness of $\tilde{\text{Gr}}_{G,C^\Theta}$ and Lemma 3.7.3.

We now prove the claim that $\sigma'$ extends to all of $C \times S$. For each $\lambda \in \mathcal{C}_X^\lambda$, the $G$-submodule $V^\lambda \subset k[X]$ induces a $G$-equivariant map of varieties $\varphi_\lambda : X \to V^\lambda \ast$, where $V^\lambda \ast$ is considered as a right $G$-module. It suffices to show that the composition $\varphi_\lambda(\sigma') : C \times S-D \to V^\lambda \ast \times G \mathcal{P}'_G$ extends for all $\lambda \in \mathcal{C}_X^\lambda$. For $\tilde{\theta} \in \mathcal{C}_X^\theta$, we have $\langle \mu, \tilde{\theta} \rangle \geq 0$ for all weights $\mu$ of $V^\lambda$. We deduce that the group homomorphism $G \to \text{GL}(V^\lambda)$ induces a natural map

\[ \tilde{\text{Gr}}_{G,C^\Theta} \to \mathcal{L}^+ \text{End}(V^\lambda)/\mathcal{L}^+ \text{GL}(V^\lambda). \]

Hence $\tau^{-1}$ induces a regular map $V^\lambda \ast \times G \mathcal{P}_G|_{\tilde{C}_D^0} \to V^\lambda \ast \times G \mathcal{P}'_G|_{\tilde{C}_D^0}$ and $\varphi_\lambda(\tau^{-1} \circ \sigma|_{\tilde{C}_D^0})$ defines a section $\tilde{C}_D^0 \to V^\lambda \ast \times G \mathcal{P}'_G$. By Beauville–Laszlo’s theorem (cf. [BD96, Theorem 2.12.1]), this implies that $\varphi_\lambda(\sigma')$ is defined on all of $C \times S$. \qed

We describe more precisely what $\text{act}_M$ is doing on $k$-points: at a single $v \in |C|$, a $k$-point of $\mathcal{M}_X$ gives an element of $(X(\mathfrak{o}_v) \cap X^\bullet(F_v))/G(\mathfrak{o}_v)$ and the map $\text{act}_M$ corresponds to the natural $G(F_v)$-action on $X^\bullet(F_v)$. For $\tilde{\mu} \in \hat{\Lambda}_G^\circ$, define the set

\[ X^\bullet(F_v)_{G; \tilde{\mu}} = \bigcup_{\tilde{\mu}' \in \hat{\Lambda}_G^\circ; \tilde{\mu}' \geq \tilde{\mu}} X^\bullet(F_v)_{G; \tilde{\mu}'}, \]
in the notation of §2.2.4. In the next subsection we prove a slightly more precise\footnote{In [SV17] the ordering \( \geq \) is defined with respect to the rational cone generated by the valuations of colors, whereas we define \( \geq \) with respect to the monoid generated by non-negative integral combinations of valuations of colors.} version of [SV17, Lemma 5.5.2]:

**Lemma 5.2.4.** Let \( \hat{\mu}, \hat{\theta} \in \hat{\Lambda}_G \). The action map sends

\[
X^\bullet(F_v)_{G; \geq \hat{\mu}} \times \left[ + \mathbb{G}_m, + \mathbb{G}_m \right] \cdot L^G \cdot \ell^\theta : L^G(k) \rightarrow X^\bullet(F_v)_{G; \geq \hat{\mu} + \hat{\theta}}.
\]

### 5.3. Reduction to \( c_{X^\bullet} = \mathbb{N}^D \)

We are interested in applying Hecke actions to \( \overline{M}_X^0 \), the closure of \( M_X^\bullet = M_X^0 = \text{Bun}_H \) in \( M_X \), since it is the most basic closure of a stratum. On the other hand, in order to determine the stratification of \( \overline{M}_X^0 \) we need a moduli description of this stack.

A first guess would be that \( \overline{M}_X^0 = (M_X^\text{univ})_{\text{red}} \), but this may not be true if \( c_{X^\bullet} := c_{X^\text{univ}} \) is not equal to \( \{ \hat{\lambda} \geq 0 \} \). In this subsection we explain how to get around this technical issue: we can always replace \( G \) by a central extension \( G' \to G \) such that \( X^\bullet = H' \setminus G' \) and \( X' := \text{Spec } k[H' \setminus G'] \), then \( \overline{M}_X' = M_X' \) and \( c_{X'} = \mathbb{N}^D \) (see Lemma 5.3.3).

This is a generalization of the need to replace \( \overline{N \setminus G}^\text{aff} \) by \( \overline{N \setminus G}^\text{aff} \) for \( \overline{G} \) a simply connected cover of \( G \) in [ABB+05, §4.1], [Sch15, §7.2] to correctly define Drinfeld’s compactification of \( \text{Bun}_N \) for an arbitrary reductive group \( G \).

#### 5.3.1. Let us first assume that \( k[G] \) is a UFD. Further, assume that \( H \) is connected, as is the case under our assumptions (Remark 3.0.1). Then the preimage of any color \( D \) in \( G \) is irreducible, and this defines a bijection between \( H \times B \)-stable divisors in \( G \) and colors; moreover, under our UFD assumption, the former are all principal.

Let \( k(G)^{\langle H \times B \rangle} \) denote the \( H \times B \)-eigenvectors of \( k(G) \). Then, since \( HB \) is open dense in \( G \), we have

\[
k(G)^{\langle H \times B \rangle} / k^\times = \mathcal{X}(H) /_{\mathcal{X}(B \cap H)} \mathcal{X}(B),
\]

where \( \mathcal{X}(H) \) is the character group of \( H \) (so \( \mathcal{X}(B) = \Lambda_G \) by definition). The valuation map gives rise to a short exact sequence

\[
0 \rightarrow \mathcal{X}(G) \rightarrow \mathcal{X}(H) /_{\mathcal{X}(B \cap H)} \mathcal{X}(B) \rightarrow \mathbb{Z}^D \rightarrow 0,
\]

which sends an element of \( k(G)^{\langle H \times B \rangle} / k^\times \) to its divisor, identified with a \( \mathbb{Z} \)-linear combination of the colors. (We have used here both the UFD property, and the fact that invertible regular functions on \( G \) are multiples of characters.)

The preimage in \( G \) of each color \( D \) defines a valuation \( \nu_{H,D} \) on \( k(G)^\times \); its restriction to \( k(G)^{\langle H \times B \rangle} \) defines a map

\[
\tilde{\nu}_{H \setminus G} : D \rightarrow (\mathcal{X}(H) /_{\mathcal{X}(B \cap H)} \mathcal{X}(B))^\vee.
\]

Composing with the second projection to \( \hat{\Lambda}_X \) gives the usual valuation map \( \rho_{H \setminus G} \). By construction we have \( \nu_{H,D}(f_{D'}) = \delta_{D,D'} \) for \( D, D' \in D \), and the sequence dual to (5.4) is

\[
0 \rightarrow \mathbb{Z} D \tilde{\rho}_{H \setminus G}(\mathcal{X}(H) /_{\mathcal{X}(B \cap H)} \mathcal{X}(B))^\vee \rightarrow \mathcal{X}(G)^\vee \rightarrow 0.
\]
5.3.2. Now we return to the case of arbitrary $G$. Let

$$1 \to Z \to \widehat{G} \to G \to 1$$

be a central extension with connected kernel $Z$ such that the derived group $[\widehat{G},\widehat{G}]$ is simply connected (such a $\widehat{G}$ always exists). Then $k[\widehat{G}]$ is a UFD ([KKLV89, Proposition 4.6], [Ive76]). We consider $H \setminus G$ as a $\widehat{G}$-spherical variety, so $H \setminus G = \widehat{H} \setminus G$ where $\widehat{H} = HZ$ is the preimage of $H$ in $\widehat{G}$. Let $\widehat{B}$ denote the Borel subgroup of $\widehat{G}$. If $H$ is connected, then $\widehat{H}$ is also connected. The colors stay the same, so $\vartheta_{H \setminus G}$ induces a short exact sequence

$$(5.5) \quad 0 \to Z^D \overset{\vartheta_{H \setminus G}}{\to} (\mathcal{A}(\widehat{H}) \times_{\mathcal{A}(B \setminus H)} \mathcal{A}(\widehat{B}))^\vee \to \mathcal{A}(\widehat{G})^\vee \to 0.$$

Let $\widehat{H}_{ab} = \widehat{H}/[\widehat{H},\widehat{H}]$, so $\mathcal{X}(\widehat{H}) = \mathcal{X}(\widehat{H}_{ab})$. We consider $[\widehat{H},\widehat{H}] \setminus \widehat{G}$ as a spherical variety for the group $G' := \widehat{H}_{ab} \times Z \widehat{G}$, where $\widehat{H}_{ab}$ acts by left translation and $\widehat{G}$ acts by right translation. Then $[\widehat{H},\widehat{H}] \setminus \widehat{G} = H' \setminus G'$ where $H' = (\widehat{H}/Z)^{\text{diag}} = H^{\text{diag}}$ is diagonally embedded in $G'$. Observe that $G' \to G$ is a central extension with kernel $\widehat{H}_{ab}$ and

$$H' \setminus G' = [\widehat{H},\widehat{H}] \setminus \widehat{G} \to \widehat{H} \setminus \widehat{G} = H \setminus G$$

is a $\widehat{H}_{ab}$-torsor. The Borel subgroup $B'$ of $G'$ is $\widehat{H}_{ab} \times Z \widehat{B}$ and $B' \cap H' = ((\widehat{B} \cap \widehat{H})/Z)^{\text{diag}}$, so (5.5) is equivalent to a short exact sequence

$$0 \to Z^D \overset{\vartheta_{H' \setminus G'}}{\to} \widetilde{\Lambda}_{H' \setminus G'}' = \ker(\mathcal{X}(B') \to \mathcal{X}(B' \cap H'))^\vee \to \mathcal{X}(\widehat{G})^\vee \to 0.$$

To summarize:

**Lemma 5.3.3.** Let $H \setminus G$ be a homogeneous spherical variety with $H$ connected. Then there exists a central extension $G' \to G$ with connected kernel $Z'$ and a spherical subgroup $H' \subset G'$ such that

(i) $|G',G'|$ is simply connected.

(ii) The covering $G' \to G$ restricts to an isomorphism $H' \cong H$. In particular, the projection $H' \setminus G' \to H \setminus G$ is a $Z'$-torsor.

(iii) The valuation map $\vartheta_{H' \setminus G'}$ embeds $Z^D \to \widetilde{\Lambda}_{H' \setminus G'}'$ as a direct summand.

By (iii), we have that $\epsilon_{H' \setminus G'} = \epsilon_{H' \setminus G'}^D = \mathbb{N}^D$ so there is no question of integrality. For a similar result, see [Bri07, Lemma 2.1.1].

**Example 5.3.4.** If we start with $H = \mathbb{G}_m$ the torus inside $G = \text{PGL}_2$, then $G' = \mathbb{G}_m \times \text{GL}_2$ and $H' = \mathbb{G}_m$ where $\mathbb{G}_m$ maps to $\text{GL}_2$ by $(\ast \ 0 \ 1)$. So $H' \setminus G' = \text{GL}_2$, where $\mathbb{G}_m$ acts by left translations and $\text{GL}_2$ by right translations. This is a $\mathbb{G}_m$-torsor over $\mathbb{G}_m \setminus \text{GL}_2$ and a $\mathbb{G}_m \times Z(\text{GL}_2)$-torsor over $\mathbb{G}_m \setminus \text{PGL}_2$.

**Proof of Lemma 5.3.2.** Let $1 \to Z' \to G' \to G \to 1$ be a central extension as in Lemma 5.3.3. Since $\epsilon_{H' \setminus G'} = \epsilon_{H' \setminus G'}^D$, there is no question of integrality and [SV17, Lemma 5.5.2] applied to the $G'$-variety $H' \setminus G'$ says that the action map sends

$$(H' \setminus G')(F_v)_{\geq \mu} \times_{G'(o_v)} G'(o_v) t^{\sum G'(o_v)} (H' \setminus G')(F_v)_{\geq \mu + \delta},$$

where $\mu, \delta \in \widetilde{\Lambda}_{H' \setminus G'}$. Since $H' \setminus G' \to H \setminus G = X^\bullet$ is a $Z'$-torsor, it is surjective on $F_v$-points (and corresponding orbits). Since $\epsilon_{H' \setminus G'}^D$ maps to $\epsilon_X^D$, we deduce that the action map sends

$$X^\bullet(F_v)_{\geq \mu} \times_{G(o_v)} G(o_v) t^{\sum G(o_v)} (F_v)_{\geq \mu + \delta}. $$
for \( \bar{\mu}, \bar{\theta} \in \bar{\Lambda}_G \). The preimage of \( \bar{G}^G(D)(k) \) in \( G(F_v) \) consists of the union of \( G(\mathcal{O}_v) \bar{G}^G(\mathcal{O}_v) \) for \( \bar{\theta}' \in \bar{\Lambda}_G, \bar{\theta}' \geq \bar{\theta} \). Since \( \bar{\theta}' \geq \bar{\theta} \) implies \( \bar{\theta}' \geq \bar{\theta} \), we deduce the claim. \( \Box \)

5.4. **Open Zastava.** Consider \( \mathcal{H}^{\lambda,0} = \mathcal{H}^\lambda ; = (X, Y, C, H) = \text{Maps}_{\text{gen}}(C, H(G/B \supset \text{pt}) \), which is an open subscheme of \( \mathcal{Y} \). Since \( M^0_X \cong \text{Bun}_H \) is smooth and \( \mathcal{Y} \) is smooth locally isomorphic to \( \mathcal{M}^0_X \) by Lemma 3.5.4, the scheme \( \mathcal{Y} \) is also smooth.

The preimage of the connected component \( A^1 \) in \( \mathcal{Y} \) is by definition \( \mathcal{H}^{\lambda,0} \). Let \( G' \to G \) be a central extension as in Lemma 5.3.3, so we have a torsor \( H'/G' \to X^\bullet \). Let \( X' = \text{Spec } k[H'/G'] \). Then \( c_{X'} = \mathbb{N}^D \) and we have an isomorphism of stacks \( X^\bullet / B' \cong X^\bullet / B \), where \( B' \) is the Borel subgroup of \( G' \). Hence,

\[
\mathcal{Y}_{X'} \cong \mathcal{Y}_{X} = \text{Maps}_{\text{gen}}(X^\bullet / B' \supset \text{pt}),
\]

and the map \( \mathcal{Y}_{X} \to \mathcal{A} \) factors through \( \pi_{X'} : \mathcal{Y}_{X'} \to \mathcal{A}_{X'} \). The base \( \mathcal{A}_{X'} \) is a disjoint union of smooth partially symmetrized powers of the curve indexed by \( \mathbb{N}^D \). For \( D = \sum_{D'} n_{D'} \cdot D' \in \mathbb{N}^D \), we will denote by \( \mathcal{Y}_{X'}^D \) the preimage of the corresponding component of \( \mathcal{A}_{X'} \). We define

\[
\{ \mathcal{Y}_{X'}^D \} = \{ \mathcal{Y}_{X'}^n \}_{D = \sum_{D'} n_{D'} \cdot D'}
\]

This implies:

**Lemma 5.4.1.** We have \( \mathcal{Y}_{X'}^{\lambda,0} \) is nonempty only if \( \lambda \geq 0 \).

Under our assumption that \( X \) only has spherical roots of type \( T \), every color \( D \in D \) belongs to \( D(\alpha) \) for some simple root \( \alpha \) of \( G \) and \( X^\bullet P_\alpha / \mathcal{R}(P_\alpha) = \mathbb{G}_m \backslash \text{PGL}_2 \).

**Lemma 5.4.2.** If \( D(\alpha) = \{ D^+_\alpha, D^-_\alpha \} \) for a simple root \( \alpha \), then for any \( n^\pm \in \mathbb{N} \), there is an isomorphism

\[
\mathcal{Y}_{X'}^{n^+D^\pm + n^-D^-} = C(n^+) \times C(n^-).
\]

**Proof.** We may assume \( c_{X'} = \mathbb{N}^D \). Then, \( \mathcal{Y}_{X'}^{n^+D^\pm + n^-D^-} \) classifies maps from the curve to \( X^\bullet / B \) which have zero valuation on every color other than those in \( D(\alpha) \), and therefore is a subscheme of \( \text{Maps}(C, (X^\bullet - \bigcup_{D \in D^-} D) / B) \). Since \( X^\bullet P_\alpha = \mathbb{G}_m \backslash P_\alpha \) is affine, its complement is the union of the colors that it does not intersect. Hence, \( (X^\bullet - \bigcup_{D \in D^-} D(\alpha)) D = (X^\bullet P_\alpha) / B = \mathbb{G}_m \backslash \text{PGL}_2 / \text{PGL}_1 = \mathbb{G}_m \backslash \mathbb{P}^1 \). By Example 3.3.1, we see that \( \text{Maps}(C, \mathbb{G}_m \backslash \mathbb{P}^1) = \text{Sym} C \times \text{Sym} C \), and it follows that the components correspond to \( \mathbb{N}^D(\alpha) \) in the natural way. \( \Box \)

**Remark 5.4.3.** For a general element \( D = \sum_{D'} n_{D'} \cdot D' \in \mathbb{N}^D \), the graded factorization property together with Lemma 5.4.2 imply that there is an open embedding \( \prod D C(n_{D'}) \to \mathcal{Y}_{X'}^\lambda \), where the product is over the disjoint locus. We will show in Lemma 6.2.1 that \( \mathcal{Y}_{X'}^{D}, D \in \mathbb{N}^D \) are precisely the connected components of \( \mathcal{Y}_{X'} \), so the open subscheme above is dense. (This also implies that the \( \mathcal{Y}_{X'}^D \) are defined intrinsically and independent of the choice of \( G' \to G \).)

**Remark 5.4.4.** If \( D \) is as above, and \( \lambda = \gamma(D) \), we can read off the length \( \text{len}(D) \) directly from \( \lambda \), if \( X^\bullet \) happens to admit a \( G \)-eigen-volume form. Namely, under this assumption, one can show that there is a character \( \gamma \in \Lambda \) such that \( \langle \gamma, \bar{v}_{D'} \rangle = 1 \) for every color \( D' \), therefore \( \text{len}(D) = \langle \gamma, \bar{\lambda} \rangle \). Indeed, for such a color \( D' \), there is a simple root \( \alpha \) such that the parabolic \( D' P_\alpha \) contains the open Borel orbit, and then \( D' P_\alpha \approx \bar{v}_{D'}(\mathbb{G}_m) \backslash P_\alpha \). For such a homogeneous space to have a \( P_\alpha \)-eigen-volume form with eigencharacter \( h \), we must have that \( \langle h + 2\rho_{N_\alpha}, \bar{v}_{D'} \rangle = 0 \), where \( 2\rho_{N_\alpha} \) is the sum of roots in the unipotent radical of \( P_\alpha \). Equivalently, since \( \langle \alpha, \bar{v}_{D'} \rangle = 1 \), this reads \( \langle h + 2\rho_G, \bar{v}_{D'} \rangle = 1 \). Therefore,

\[
\text{len}(D) = \langle h + 2\rho_G, \bar{\lambda} \rangle,
\]

which we can unambiguously denote by \( \text{len}(\lambda) \).
5.5. Proof of Theorem 5.1.1.

5.5.1. Idea of the proof. Let us give a set-theoretic idea for the proof of Theorem 5.1.1, as well as a guide to new notation we are about to introduce. The discussion here is not rigorous, using sets as avatars for geometric objects.

We have been using the notation $X^\bullet(F)_{G,\bar{\theta}}$, or $(X^\bullet(F)/K)_{G,\bar{\theta}}$ to denote the set of points in the $K$-orbit parametrized by $\bar{\theta} \in \mathcal{V} \cap \hat{\Lambda}$, where $K = G(\mathfrak{a})$. The stratum $\mathcal{M}^\theta_X$ of the global model corresponds to $(X(\mathfrak{a})/K)_{G,\bar{\theta}}$, in the sense that it is determined by the condition that the “G-valuation” of maps in this stratum, at points where they fail to land in $X^\bullet$, is given by $\theta$.

Similarly, $T(\mathfrak{a})N(F)$-orbits on $X^\circ(F)$ are parametrized by $\hat{\Lambda}$, and let us denote by $X(F)_{B;\hat{\lambda}}$ the subset of points which: (1) belong to $X^\circ(F)$, and (2) belong to the $T(\mathfrak{a})N(F)$-orbit parametrized by $\hat{\lambda} \in \hat{\Lambda}_X$. As with the global model, the central fibers of the stratum $Y^\lambda_{X,\bar{\theta}}$ of the Zastava space correspond to $(X(\mathfrak{a})/B(\mathfrak{a}))_{G,\bar{\theta}}$.

The following facts will be proven about the space $Y^\lambda_{X,\bar{\theta}}$:

- It is nonempty only if $\bar{\lambda} \geq \bar{\theta}$ (see Lemma 5.4.1 and Corollary 5.5.6). This is essentially a statement about the image of $X(\mathfrak{a})$ in $X//N(F)$.
- It contains $Y^\lambda_{X,\bar{\theta}}$ as an open dense (see Lemma 5.5.7). This is a geometric statement, and it follows from the constructions that we describe below.

Theorem 5.1.1 says that the geometric analog of the action map

$$\text{act} : X^\bullet(\mathfrak{a}) \times^K Kt^\theta K \to X(\mathfrak{a})_{G,\bar{\theta}}$$

is birational and proper. (The closures are also understood here in the “geometric” topology, see Lemma 5.2.4.)

To prove this, we fix $\bar{\theta} \in \mathcal{V}_-$, which will not appear in the notation, and work with $B(\mathfrak{a})$-orbits, defining spaces whose central fibers satisfy the following set-theoretic analogies:

$$Z^\lambda_{-\bar{\theta}, \bar{\lambda}} \quad \text{and} \quad \overline{X^\bullet(\mathfrak{a})_{B;\bar{\lambda} - \bar{\theta}}} \quad \text{and} \quad \overline{(T(\mathfrak{a})t^\bar{\theta}N(F) \cap \overline{Kt^\bar{\theta}K})/B(\mathfrak{a})}$$

$$Z^\lambda_{-\bar{\theta}, \bar{\lambda}, \bar{\theta}', \bar{\eta}} \quad \text{and} \quad \overline{X^\bullet(\mathfrak{a})_{G,\bar{\theta}'}} \times^B_{B;\bar{\lambda} - \bar{\theta}} \overline{(T(\mathfrak{a})t^\bar{\theta}N(F) \cap \overline{Kt^\bar{\theta}K})/B(\mathfrak{a})}$$

Here, $\bar{\eta} \geq \bar{\theta}$ (and antidominant), so that the Cartan double coset $Kt^\bar{\eta}K$ belongs in the affine Grassmannian to the closure of $Kt^\bar{\theta}K$. Both of the spaces above are subschemes of the preimage of $X(\mathfrak{a})_{B;\bar{\lambda}}$ in $X^\bullet(\mathfrak{a}) \times^K Kt^\theta K$ — in fact, substacks, in the appropriate setting. Indeed, stratifying $Kt^\theta K$ by the “Mirković–Vilonen (MV) cycles” corresponding to its intersection with the horocycles $Kt^\theta N(F)$, we obtain a stratification of this space by

$$\overline{\left(X^\bullet(\mathfrak{a}) \times^K \left(Kt^\theta N(F) \cap \overline{Kt^\theta K}\right)/B(\mathfrak{a}) \cap \text{act}^{-1}(X(\mathfrak{a})/B(\mathfrak{a}))_{B;\bar{\lambda}}\right)}$$

(where act denotes the action map). Note that $Kt^\theta N(F)/B(\mathfrak{a}) = K \times^B(\mathfrak{a}) T(\mathfrak{a})t^\bar{\theta}N(F)/B(\mathfrak{a})$, hence the above can also be written

$$\overline{\left(X^\bullet(\mathfrak{a}) \times^B(\mathfrak{a}) (T(\mathfrak{a})t^\bar{\theta}N(F) \cap \overline{Kt^\theta K})/B(\mathfrak{a}) \cap \text{act}^{-1}(X(\mathfrak{a})/B(\mathfrak{a}))_{B;\bar{\lambda}}\right)}.$$
This is a combination of the statements that $X^\bullet(o)$ is (tautologically) open dense in $\overline{X^\bullet(o)}$ (allowing us to take $\hat{\theta}' = 0$), that the Cartan double coset $K^\theta K$ is (again tautologically) open dense in its closure, and that the MV-cycle $K^\theta K \cap K^\theta N(F)$ is open in it.

The open MV stratum on the affine Grassmannian $K \backslash G(F)$ meets the coset $K \backslash K^\theta K$ along the $N(o)$-orbit $K \backslash K^\theta N(o)$. Therefore, the quotient

$$(T(o)^\theta N(F) \cap K^\theta K)/B(o)$$

is just a point ($\hat{\theta}$ is anti-dominant). Thus,

$$X^\bullet(o)_{B,\lambda-\hat{\theta}} \times_{B(o)} (T(o)^\theta N(F) \cap K^\theta K)/B(o) \cong (X^\bullet(o)/B(o))_{B,\lambda-\hat{\theta}},$$

which, on the other hand, can be identified as an open dense subset of $(X(o)/B(o))_{B,\hat{\theta}}$. Thus, in the geometric setting, the action map (5.8), restricted to the subsets with $B$-valuation equal to some (any) $\hat{\lambda}$, is indeed birational. On the other hand, the map $\gamma^\lambda : M_X$ is smooth for large $\lambda$ (Corollary 3.5.2), proving the birationality of (the geometric version of) (5.8).

5.5.2. We now turn to the actual proof of Theorem 5.1.1.

Since $\overline{Gr_{G,C}^\lambda}$ lives over $C^\lambda$, we can factor $\text{act}_M$ into

$$(5.9) \quad M_X \times \overline{Gr_{G,C}^\lambda} \xrightarrow{\text{act}_{C^\lambda}} M_X \times C^\lambda \xrightarrow{pr_1} M_X$$

where $\text{act}_{C^\lambda}$ is the naturally induced map over $C^\hat{\lambda}$.

**Lemma 5.5.3.** Let $\Theta \in \text{Sym}^\infty(c_X - 0)$.

(i) The preimage of $M_X^\Theta$ in $M_X \times \overline{Gr_{G,C}^\Theta}$ under $\text{act}_M$ is contained in the open substack $Bun_H \times \overline{Gr_{G,C}^\Theta}$.

(ii) The image $\text{act}_M(Bun_H \times \overline{Gr_{G,C}^\Theta}) \subset M_X$ contains $M_X^\Theta$ as an open dense substack.

**Proof.** Statement (i) follows from the description of $\text{act}_M$ on $k$-points and Lemma 5.2.4.

To simplify notation, we give the proof of (ii) in the case when $\Theta = [\hat{\theta}], \hat{\theta} \neq 0$ is a singleton partition. The general case is entirely analogous.

Recall that $M_X^\Theta$ is naturally a substack of $M_X \times C$ and $pr_1$ is identity on this substack. Since $\overline{Gr_G^\hat{\theta}}$ is irreducible, it therefore suffices to show that for every connected component $U$ of $Bun_H$, the irreducible image $M_U := \text{act}_C(U \times \overline{Gr_G^\hat{\theta}})$ contains its intersection with $M_X^\Theta$ as a nonempty open substack.

First we show that $M := \text{act}_C(Bun_H \times \overline{Gr_G^\hat{\theta}})$ contains $M_X^\Theta$. It is easy to see that for every connected component $U$ of $Bun_H$, the image $M_U$ contains a point of $M_X^\Theta$ over every point $v \in |C|$. It follows from Lemma A.4.6 that $M \subset M_X \times C$ is stable under generic-Hecke modifications away from the marked point in $C$. Since these generic-Hecke modifications act transitively on the stratum $M_X^\Theta$ (Proposition A.4.4), we deduce that $M$ contains all of $M_X^\Theta$.

The previous paragraph and Lemma 5.2.4 imply that

$$M_X^\Theta = M - \bigcup_{\hat{\theta}' > \hat{\theta}} \text{act}_C(M_X \times \overline{Gr_G^{\hat{\theta}'}}),$$

which shows that $M_X^\Theta$ is open in $M$. \hfill \square

As a corollary, we can now prove Theorem 5.1.1(i):
Proof of Theorem 5.1.1(i). Let $M$ denote an irreducible component of $\overline{M}_X^0$. Then $M' := \text{act}_M(M \times \overline{\Gr}^G_{G,C})$ is an irreducible closed substack of $M$, and since $M$ contains a connected component of $\text{Bun}_H$, Lemma 5.5.3(ii) implies that $M' \cap \overline{M}_X^0$ is dense in $M'$. It follows that $\overline{M}_X^0$ is dense in $\text{act}_M(\overline{M}_X^0 \times \overline{\Gr}^G_{G,C})$. \(\square\)

5.5.4. Base change to Zastava model. Fix $\tilde{\theta} \in c^-_X - 0$ and a point $v \in |C|$. Consider the restriction of $\text{act}_M$ to $M_X \times \overline{G}_{B,C} \to M_X$, which is the fiber of $\text{act}_C$ over $v \to C = G^{\tilde{\theta}}$.

Let us consider for $\tilde{\lambda} \in c_X$ the fiber product diagram

$$
\begin{array}{ccc}
Z_v^{\tilde{\lambda},\tilde{\nu}} & \xrightarrow{\text{act}_Y} & Y_v^{\tilde{\lambda}} \\
\downarrow & & \downarrow \\
\overline{M}_X^0 \times \overline{\Gr}^G_{B,C,v} & \xrightarrow{\text{act}_M} & M_X
\end{array}
$$

An $S$-point of $Z_v^{\tilde{\lambda},\tilde{\nu}}$ consists of the data $(\sigma, \mathcal{P}_G, \mathcal{P}'_B, v, \tau)$ where

- $(\sigma, \mathcal{P}_G) \in \overline{M}_X^0$,
- $\mathcal{P}'_B \in \text{Bun}_B^{\tilde{\lambda}}$ is a $B$-structure on a $G$-bundle $\mathcal{P}'_B := G \times_B \mathcal{P}'_B$,
- $\tau : \mathcal{P}'_G|_{(c-v) \times S} \cong \mathcal{P}'_G|_{(c-v) \times S}$ is a modification inducing a point in $\overline{\Gr}^\theta_B$ such that $\tau^{-1} \circ \sigma$ generically lands in $X^\circ \times_B \mathcal{P}'_B$.

Let $\hat{y} \to y$ denote the Zariski locally trivial $L^+ B$-torsor parametrizing $(\sigma, \mathcal{P}_B) \in y$ and a trivialization $\mathcal{P}_B|_{\mathcal{C}_v} \cong \mathcal{P}_B|_{\mathcal{C}_v}$, and let $\hat{y}_0 \to y_0$ be the restriction to $\overline{M}_X$. (We will use the index 0 for the same purpose on the strata of $y$.)

Proposition-Construction 5.5.5.

(i) The fiber product $Z_v^{\tilde{\lambda},\tilde{\nu}}$ admits a stratification by

$$
Z_v^{\tilde{\lambda},\tilde{\nu}} := \hat{y}_0 \times (L^+ T \cdot t^\nu \cdot LN \cap L^+ G \cdot t^\theta \cdot L^+ G)/L^+ B,
$$

where $\tilde{\nu}$ ranges over the weights of the irreducible $\tilde{G}$-module $V^\tilde{\theta}$.

(ii) We have an isomorphism at the level of reduced schemes

$$
Z_v^{\tilde{\lambda},\tilde{\nu}} \cong \hat{y}_0^\lambda \times (S^\nu \cap \overline{\Gr}^\tilde{\theta}_G).
$$

where $\hat{y}_0^\lambda \times -$ means $\hat{y}_0 \times L^+ B$.

(iii) The open stratum corresponds to $\tilde{\nu} = \tilde{\theta}$. More precisely, we have

$$
Z_v^{\tilde{\lambda},\tilde{\theta},\tilde{\nu}} \cong \hat{y}_0^\lambda \times v,
$$

where $v$ corresponds to the embedding $\{t^\tilde{\theta}\} \hookrightarrow \overline{\Gr}^G_{B,v}$.

Proof. Recall that $L^+ G \cdot t^\theta \cdot L^+ G$ has a stratification by intersecting with $L^+ G \cdot t^\nu \cdot LN$. If we take the quotient on the left by $L^+ G$, then under the identification $L^+ G \setminus LG \cong \Gr_G : g \mapsto g^{-1}$, we have described above the stratification of $\overline{\Gr}^\omega_G$ by MV cycles $\overline{\Gr}^\omega_G \cap S^{-\tilde{\nu}}$, where $\omega$ denotes the longest element of the Weyl group. It is known by [MV07, Theorem 3.2] that $\overline{\Gr}^\omega_G \cap S^{-\tilde{\nu}}$ is non-empty precisely when $-\tilde{\nu}$ is a weight of $V^{-\omega(\tilde{\theta})}$, and the open stratum corresponds to when $-\tilde{\nu}$ equals the highest weight $-\tilde{\theta}$, where $\tilde{\theta}$ is antidominant.
Now let $(\sigma, \mathcal{P}_G, \mathcal{P}_B, \tau)$ be an $S$-point of $Z_v^{\lambda, \hat{\lambda}}$. The restriction of $(\mathcal{P}_G, \mathcal{P}_B, \tau)$ to $\hat{C}_v$ gives a point in $L^+G \setminus (L^+G \setminus t^\theta \cdot L^+G/L^+B$. Therefore, by the previous paragraph, we can stratify $Z_v^{\lambda, \hat{\lambda}}$ by the preimages of
\[
L^+G \setminus (L^+G \setminus t^\theta \cdot L^+G \cap L^+G \cdot t^\varphi \cdot LN)/L^+B.
\]
Suppose our $S$-point lies in such a stratum corresponding to $\bar{v}$. In particular, $\tau$ corresponds to a point in $L^+B \setminus (\Gr_B^r)_{\text{red}}$, which means that there exists a $B$-bundle $\mathcal{P}_B|_{\hat{C}_v}$ on $\mathcal{P}_G|_{\hat{C}_v}$ such that $\tau$ gives an isomorphism of generic $B$-bundles $\mathcal{P}_B|_{\hat{C}_v} \cong \mathcal{P}_B|_{\hat{C}_v}$. By Beauville–Laszlo’s theorem, the datum $(\mathcal{P}_B'|C_v, \mathcal{P}_B|_{\hat{C}_v}, \tau)$ descends to a $B$-structure $\mathcal{P}_B$ on $\mathcal{P}_G$ such that $\mathcal{P}_B'|C_v \cong \mathcal{P}_B|_{C_v}$. Then $(\sigma, \mathcal{P}_B) \in \mathcal{Y}_G^{\bar{v}}(S)$ and $(\sigma, \mathcal{P}_B, \mathcal{P}_B', \nu, \tau) \in Z_v^{\lambda-\bar{\nu}, \hat{\lambda}}(S)$. The above procedure can be reversed to see that $Z_v^{\lambda-\bar{\nu}, \hat{\lambda}}$ is equal to the entire stratum. This shows (i).

Observe that $L^+T \cdot t^\varphi \cdot LN = LN \cdot t^\varphi \cdot L^+B$ and there is a map from $(LN \cdot t^\varphi \cdot L^+B \cap L^+G \cdot t^\theta \cdot L^+G)/L^+B$ to $S^\theta \cap \Gr_{\hat{G}}$ which is an isomorphism at the level of reduced schemes. Now (ii) follows from (i).

The open stratum $Z_v^{\lambda-\bar{\nu}, \hat{\lambda}}$ corresponds to the open stratum $\Gr_{\hat{G}}^{\nu_0(\hat{\theta})} \cap S^{-\hat{\theta}}$, when $\bar{v} = \hat{\theta}$. By [MV07, (3.6)], we have $S^\theta \cap \Gr_{\hat{G}} = \{t^\hat{\theta}\}$ so (iii) is a special case of (ii). \hfill \Box

Observe that $\tilde{M}_X^{\theta} \times \Gr_{G,v}^{\theta}$ has a stratification by $\tilde{M}_X^{\theta} \times \Gr_{G,v}^{\theta}$ for those $\hat{\Theta}' \in \Sym^\infty(\epsilon_X - 0)$ such that the stratum $\tilde{M}_X^{\theta}$ belongs to $\tilde{M}_X^{\theta}$ — still to be determined, see Lemma 5.6.2 — and those $\bar{\eta} \in -\hat{\Lambda}_G^{\bar{v}}$ such that $\bar{\eta} \geq \hat{\theta}$ (equivalently, $\bar{\eta}$ is a weight of $V^\bar{v}$). Let $Z_v^{\lambda, \hat{\lambda}, \hat{\Theta}', \bar{\eta}}$ denote the preimage of the corresponding stratum in $Z_v^{\lambda, \hat{\lambda}}$, so we have a Cartesian square\
\[
\begin{array}{ccc}
Z_v^{\lambda, \hat{\lambda}, \hat{\Theta}', \bar{\eta}} & \rightarrow & \mathcal{Y}_X^{\hat{\lambda}} \\
\downarrow & & \downarrow \\
\tilde{M}_X^{\hat{\Theta}'} \times \Gr_{G,v}^{\hat{\eta}} & \rightarrow & \tilde{M}_X^{\theta}
\end{array}
\]
This diagram now has no dependence on $\hat{\theta}$ and is defined entirely with respect to $\bar{\eta}$. Proposition 5.5.5 implies that there is a stratification
\[
Z_v^{\lambda, \hat{\lambda}, \hat{\Theta}', \bar{\eta}} = \bigcup_{\bar{v}} Z_v^{\lambda-\bar{\nu}, \lambda, \hat{\Theta}', \bar{\eta}}
\]
where $\bar{v}$ runs through the weights of $V^\bar{v}$, and $Z_v^{\lambda-\bar{\nu}, \lambda, \hat{\Theta}', \bar{\eta}}$ admits a map to $\mathcal{Y}_X^{\lambda-\bar{\nu}, \hat{\Theta}'}$. The open stratum is
\[
Z_v^{\lambda-\bar{\nu}, \lambda, \hat{\Theta}', \bar{\eta}} \cong \mathcal{Y}_X^{\lambda-\bar{\eta}, \hat{\Theta}'} \times \{t^\hat{\theta}\}.
\]

We will make special use of the case $\hat{\Theta}' = 0$ and $\bar{\eta} = \hat{\theta}$ because Lemma 5.5.3 implies that $\mathcal{Y}_X^{\lambda, \hat{\Theta}' = 0}$ is contained in the images of $Z_v^{\lambda, \hat{\lambda}, \hat{\Theta}', \bar{\eta}} \rightarrow \mathcal{Y}^\lambda$ over all $v \in C$. Note that $Z_v^{\lambda-\bar{\nu}, \lambda, 0, \theta} = \mathcal{Y}_X^{\lambda-\bar{\nu}, \hat{\Theta}'}$.

Recall that $\epsilon_X^{\theta}$ denotes the monoid generated by $\nu_D$ for $D \in \mathcal{D}$.

**Corollary 5.5.6.** Let $\hat{\theta} \in \epsilon_X^{\theta} - 0$.

1. The scheme $\mathcal{Y}_X^{\lambda, \hat{\Theta}'}$ is nonempty only if $\hat{\lambda} \geq \hat{\theta}$.
2. We have an isomorphism $(\mathcal{Y}_X^{\theta, \hat{\Theta}})_{\text{red}} \cong C$ over the diagonal $C \hookrightarrow A^\hat{\Theta}$.
3. The single point in the central fiber $\mathcal{Y}_X^{\theta, \hat{\Theta}}$ corresponds to $t^\hat{\theta} \in S^\theta \cap \Gr_{\hat{G}}^{\hat{\Theta}'}$. 
Proof. As we remarked above, every point of \( Y_{\nu}^\lambda,\hat{\theta} \) is contained in the image of \( Z_{\nu}^\lambda,\hat{\lambda},0,\hat{\theta} \) for some \( v \in \{C\} \). By the description of the stratification of \( Z_{\nu}^\lambda,\hat{\lambda},0,\hat{\theta} \), the latter is nonempty only if \( Y_{\nu}^\lambda,\nu,\hat{\theta} \) is nonempty for some \( \nu \). This implies that \( \lambda \geq \nu \) by Lemma 5.4.1. Since \( \nu \geq \hat{\theta} \), we deduce (i).

If \( \lambda = \hat{\theta} \), then \( Y_{\nu}^\theta,\nu,\hat{\theta} \) is only nonempty when \( \nu = \hat{\theta} \), in which case \( Y_{\nu}^\theta = pt \) and \( Z_{\nu}^\theta,\theta,0,\theta = \{t^\theta\} \).

By moving the point \( v \) around, we get a surjection \( C \to Y_{\nu}^\theta,\theta \) and it must be an isomorphism (on reduced schemes) since the composition with \( \pi : Y_{\nu}^\theta,\theta \to A^\theta \) gives the diagonal embedding. \( \square \)

Let \( Y_{\nu}^\lambda,\theta \) denote the disjoint locus \( Y_{\nu}^\lambda,\theta \times (Y_{\nu}^\theta,\theta)_{\text{red}} \). Observe that the composition \( Y_{\nu}^\lambda,\theta \times v \hookrightarrow Y_{\nu}^\lambda,\theta \times v = Z_{\nu}^{\lambda,\theta,\lambda,0,\hat{\theta}} \to Y_{\nu}^\lambda \) coincides with the composition \( Y_{\nu}^\lambda,\theta \times v \hookrightarrow Y_{\nu}^\lambda,\theta \times Y_{\nu}^\theta,\theta \to Y_{\nu}^\lambda \) where the second map is given by the graded factorization property.

Lemma 5.5.7. Let \( \hat{\theta} \in \epsilon_X - 0 \). Then:

(i) The open embedding \( Y_{\nu}^\lambda,\theta \times v \to Y_{\nu}^\lambda,\theta \) given by the graded factorization property is dense.

(ii) For \( \lambda \) large enough, the open stratum \( Y_{\nu}^\lambda,\theta \times v \to Z_{\nu}^{\lambda,\theta,0,\hat{\theta}} \) is dense.

Proof. First observe that by Lemma 3.5.4 we may always assume that \( \lambda \) is large enough so that the conditions of Corollary 3.5.2 hold: namely, \( Y \to M_X \) is smooth with connected fibers.

By definition, \( Y_{\nu}^\lambda,\theta \) is the preimage of \( M_X^\theta \). Now let \( V \) be a connected component of \( M_X^\theta \) that intersects the image of \( Y_{\nu}^\lambda \). Then \( Y_{\lambda}^{\nu,\lambda,\theta} := Y_{\nu}^\lambda \times_{M_X} V \) is a nonempty connected component of the smooth scheme \( Y_{\nu}^\lambda,\theta \). Lemma 5.5.3 implies that \( V \) lies in \( \operatorname{act}_M(U \times_p G_C) \), where \( U \) is a connected component of \( \text{Bun}_H \). Consider the fiber product diagram

\[
\begin{array}{ccc}
Z_{\nu}^{\lambda,\theta,0,\hat{\theta}} & \longrightarrow & Y_{\nu}^\lambda \\
\downarrow & & \downarrow \\
\text{Bun}_H \times \tilde{G}_{C} & \longrightarrow & M_X \\
\end{array}
\]

which is the analog of (5.11) where we allow \( v \) to vary. The fibers of \( Y \to M_X \) are irreducible, so \( Z_{\nu}^{\lambda,\theta,0,\hat{\theta}} := Z_{\nu}^{\lambda,\theta,0,\hat{\theta}} \times_{\text{Bun}_H} U \) is irreducible and the image of

\[
Z_{\nu}^{\lambda,\theta,0,\hat{\theta}} \to Y_{\nu}^\lambda
\]

contains \( Y_{\nu}^\lambda \) as a dense open. Proposition 5.5.5 (twisted by \( C \)) implies that \( Z_{\nu}^{\lambda,\theta,0,\hat{\theta}} \) has a stratification \( \bigcup_{\tilde{\nu}} Z_{\nu}^{\lambda,\nu,\lambda,0,\hat{\theta}} \) over the weights \( \tilde{\nu} \) of \( V^{\theta} \), and \( Z_{\nu}^{\lambda,\nu,\lambda,0,\hat{\theta}} \) maps to \( Y_{\nu}^{\nu,\nu,\hat{\theta}} \times_{\text{Bun}_H} U \). In particular, \( Y_{\nu}^{\lambda,\nu,\lambda,0,\hat{\theta}} := Y_{\nu}^{\lambda,\nu,\lambda,0,\hat{\theta}} \times_{\text{Bun}_H} U \) is nonempty for some \( \nu \). Since \( \nu \geq \hat{\theta} \), Corollary 3.5.2(ii) implies that \( Y_{\nu}^{\lambda,\nu,\lambda,0,\hat{\theta}} \) is also nonempty. Therefore the open stratum \( Z_{\nu}^{\lambda,\nu,\lambda,0,\hat{\theta}} \times_{\text{Bun}_H} C \) is nonempty. By Corollary 5.5.6, we can identify \( C \cong (Y_{\nu}^{\lambda,\theta,0})_{\text{red}} \), and the map

\[
y_{\nu}^{\lambda,\nu,\lambda,0,\hat{\theta}} \times_{\text{Bun}_H} C \hookrightarrow Z_{\nu}^{\lambda,\nu,\lambda,0,\hat{\theta}} \to Y_{\nu}^\lambda
\]

coincides with the open embedding \( Y_{\nu}^{\lambda,\nu,\lambda,0,\hat{\theta}} \times_{\text{Bun}_H} C \to Y_{\nu}^\lambda \) given by graded factorization. Then \( Y_{\nu}^{\lambda,\nu,\lambda,0,\hat{\theta}} \times_{\text{Bun}_H} C \) is a nonempty open subscheme of the irreducible component \( Y_{\nu}^{\lambda,\theta} \), so it must be dense.

To show (ii), note that a priori the preimage of \( Y_{\nu}^{\lambda,\theta} \) in \( Z_{\nu}^{\lambda,\theta,0,\hat{\theta}} \) is contained in a finite union of \( Z_{\nu}^{\lambda,\theta,0,\hat{\theta}} \) for connected components \( U \) of \( \text{Bun}_H \). However we saw above that the open stratum \( Y_{\nu}^{\lambda,\theta,0,\hat{\theta}} \times C \) is nonempty, and therefore dense in \( Z_{\nu}^{\lambda,\theta,0,\hat{\theta}} \), for each such \( U \). \( \square \)
In the proof above, we have essentially shown Theorem 5.1.1(ii) along the way:

**Proof of Theorem 5.1.1(ii).** To simplify notation, we only show the case $\Theta = [\theta]$. The multipoint version is proved in exactly the same way. We continue to use the notation from the previous proof of Lemma 5.5.7. By Corollary 3.5.2 and the base change diagram (5.10), it suffices to show that

$$Z^2,\lambda \rightarrow y_\lambda \times \overline{\mathcal{M}}^\theta_\mathcal{X}$$

is birational, for $\lambda$ large enough. Restricting to open dense subsets, it is enough to show that

$$Z^2,\lambda,0,\theta \rightarrow y_\lambda \times \overline{\mathcal{M}}^\theta_\mathcal{X}$$

is birational. It follows from Lemma 5.5.7 that $y_\lambda-\theta,0,\theta \times C$ is a dense open in both the target and source. \hfill $\square$

5.5.8. Recall that for an arbitrary algebraic group $H$, the algebraic fundamental group $\pi_1(H)$ is defined as the quotient of the coweight lattice by the coroot lattice of the reductive group $H/H_u$, where $H_u$ is the unipotent radical of $H$. For $\mu \in \pi_1(H)$, let $\text{Bun}^\mu_H$ denote the corresponding connected component of $\text{Bun}_H$ and let $\hat{\mu} \overline{\mathcal{M}}^\mu_X$ be its closure in $\mathcal{M}_X$.

**Corollary 5.5.9.** Let $\hat{\Theta} \in \text{Sym}^\infty(\xi_X-0)$. Then the set of irreducible components of $\overline{\mathcal{M}}^\hat{\Theta}_X$ is in bijection with $\pi_1(H)$, where $\mu \in \pi_1(H)$ corresponds to

$$\hat{\mu} \overline{\mathcal{M}}^\mu_X := \text{act}_{\mathcal{M},v}(\hat{\mu} \overline{\mathcal{M}}^0_X \times \hat{\Theta} \overline{\mathcal{G}}_{G,C^\oplus}).$$

**Proof.** It follows from Theorem 5.1.1 that the irreducible components of $\overline{\mathcal{M}}^\hat{\Theta}_X$ are in bijection with the irreducible components of $\text{Bun}_H \times \hat{\Theta} \overline{\mathcal{G}}_{G,C^\oplus}$. Since $\hat{\Theta} \overline{\mathcal{G}}_{G,C^\oplus}$ is irreducible, the latter are in bijection with $\pi_0(\text{Bun}_H) = \pi_1(H)$. \hfill $\square$

We will let $\hat{\mu} \overline{\mathcal{M}}^\mu_X := \hat{\mu} \overline{\mathcal{M}}^\mu_X \cap \mathcal{M}^\hat{\Theta}_X$ denote the corresponding connected component of $\mathcal{M}^\hat{\Theta}_X$ (which is smooth).

5.5.10. Mirković–Vilonen cycles. We finish this subsection by proving a result that will be used in the following sections. The goal here is to show that the Mirković–Vilonen cycles in the $\theta$-stratum of the affine Grassmannian map, generically, to the $\hat{\theta}$-stratum of the global model of $X$, under the action map.

Fix $v \in |C|$ and $\theta \in \xi_X-0$. Consider the restriction of $\text{act}_{\mathcal{M},v}$ to

$$\text{pt} \times \hat{\Theta} \overline{\mathcal{G}}_{G,v} \rightarrow \text{Bun}_H \times \hat{\Theta} \overline{\mathcal{G}}_{G,v} \rightarrow \overline{\mathcal{M}}^\theta_X,$$

where $\text{pt} \rightarrow \text{Bun}_H$ corresponds to the trivial $H$-bundle. Note that the map (5.12) above can be extended to a map

$$\text{act}_v : \hat{\Theta} \overline{\mathcal{G}}_{G,v} \times (L^+X/L^+G) \rightarrow \mathcal{M}_X$$

using Beauville–Laszlo’s theorem: a point of the left hand side consists of a $G$-bundle $\mathcal{P}_G$ and a trivialization $\tau : \mathcal{P}_G|C-v \cong \mathcal{P}_G^0|C-v$ such that $\tau^{-1} \circ x_0 : C-v \rightarrow X \times G \mathcal{P}_G$ is regular when localized at $a_v$. Here $x_0 : C \rightarrow X \times G \setminus \mathcal{P}_G = X \times C$ denotes the section corresponding to the base point $x_0 \in X^\circ$. Thus $\text{act}_v(\mathcal{P}_G,\tau) := (\mathcal{P}_G,\tau^{-1} \circ x_0) \in \mathcal{M}^\theta_X$ is well-defined.
Define $G^\cdot_G \subset G^\cdot_G$ to be the open subscheme equal to the preimage of the stratum $M^\cdot_X$ under (5.12). We can also identify $\bar{G}^\cdot_G = G^\cdot_G \times_{L^+G} (L^\cdot X/L^+G)$.

Taking central fibers with respect to $v$, the restriction of $\act_v$ to a semi-infinite orbit factors through

\[(5.14) \quad S^\lambda \cap \bar{G}^\cdot_G \twoheadrightarrow Y^\lambda \times_{M^\cdot_X} \bar{M}^\cdot_X,\]

where $\lambda$ is a weight of $V^\cdot$ and we consider $(Y^\lambda)_{\text{red}}$ as a subscheme of $S^\lambda$ via Lemma 4.3.2. Note that $S^\lambda \cap \bar{G}^\cdot_G$ is isomorphic to the closed stratum $Z^\alpha_\lambda$ from Proposition 5.5.5. Under this identification (5.14) coincides with the restriction of the map $\act_G : Z^\alpha_\lambda \rightarrow Y^\lambda$ from (5.10).

Observe that $S^\theta \cap G^\cdot_G = \{t^\theta\}$ is contained in $G^\cdot_G$. We will use this to deduce:

**Lemma 5.5.11.** Let $\lambda, \hat{\theta}$ as above. Then $S^\lambda \cap G^\cdot_G$ intersects every irreducible component of $S^\hat{\theta}$ of dimension $(\rho_G, \lambda - \hat{\theta})$.

**Proof.** Let $Z$ denote an irreducible component of $S^\lambda \cap G^\cdot_G$ of dimension $d = \langle \rho, \lambda - \hat{\theta} \rangle$. Let $\overline{Z}$ denote its closure in $S^\lambda \cap G^\cdot_G$. Then the proof of [MV07, Theorem 3.2], which we briefly recall in the next paragraph, shows that $\overline{Z}$ contains $t^\hat{\theta} \in G^\cdot_G$. Thus $\overline{Z} \cap G^\cdot_G$ is open and nonempty, hence dense in $\overline{Z}$.

Since the boundary of $S^\lambda$ in $S^\lambda$ is a hyperplane section (Proposition 4.4.1), $Z - \overline{Z}$ contains an irreducible component of dimension $d - 1$ inside $S^\lambda \cap G^\cdot_G$ for $\lambda_1 < \lambda$. In this way we produce a sequence $\lambda = \lambda_0, \ldots, \lambda_d$ and irreducible components of $S^\lambda \cap G$ of dimension $d - i$. The only weight $\lambda_d$ of $V^\cdot$ such that $(\rho_G, \lambda - \lambda_d) \geq d$ is $\lambda_d = \hat{\theta}$, so $Z$ must contain $S^\theta \cap G^\cdot_G = \{t^\theta\}$. \Halmos

**5.6. Closure relations and components in the global model.** Let $\Theta, \Theta' \in \Sym^{\infty}(e^{-\cdot}_{X} - 0)$. Consider $\Theta' - \Theta$ as a formal sum in $\bigoplus_{\theta \in e^{-\cdot}_{X} - 0} \mathbb{Z}[\theta]$. We say that

\[\Theta' \succeq \Theta\]

if $\Theta' - \Theta$ can be written as a sum of formal differences $[\theta'] - [\theta]$ where $\theta, \theta' \in e^{-\cdot}_{X}$ and $\theta' \succeq \theta$. Note that we allow $\theta = 0$ (in which case $[0] = 0$), and for general $\theta, \theta'$ as above, it is not necessarily the case that $\theta - \theta' \in \mathcal{V}$.

**Proposition 5.6.1.** Let $\Theta, \Theta' \in \Sym^{\infty}(e^{-\cdot}_{X} - 0)$. We have that $M^\Theta_X$ lies in the closure of $M^\Theta_X$ if and only if there exists $\Theta'' \in \Sym^{\infty}(e^{-\cdot}_{X} - 0)$ such that $\Theta$ refines $\Theta''$ and $\Theta' \succeq \Theta''$.

The reader may want to skip the proof of this proposition at first reading, and focus on the corollaries that follow. Note that the proof will use Zastava models, despite the fact that the statement is about the global model. The proof of the proposition starts with the following special case:

**Lemma 5.6.2.** The closure of $M_{\Theta}^\cdot_X$ in $M_{\Theta}^\cdot_X$ intersects $M_{\Theta}^\cdot_X$ only if $\Theta \succeq 0$.

**Proof.** Let $\bar{\Theta}$ correspond to a stratum such that $M_{\bar{\Theta}}^\cdot_X$ intersects $M_{\Theta}^\cdot_X$. Then by Corollary 3.5.2 there exists $\lambda$ such that $Y^{\lambda, \Theta}$ intersects the closure of $Y^{\lambda, 0}$ in $Y^\lambda$. Now consider the torsor $H^\cdot \backslash G^\cdot \rightarrow X^\cdot$ from Lemma 5.3.3. Let $X^\cdot = \Spec k[H^\cdot \backslash G^\cdot]$ considered as an affine $G^\cdot$-variety. The corresponding compactified Zastava model $\bar{Y}^\cdot_{X^\cdot} \rightarrow A^\cdot_{X^\cdot}$ is indexed by $D \in e^{-\cdot}_{X^\cdot} = \mathbb{N}^D$. Since $X^\cdot / B^\cdot \cong X^\cdot / B$ as stacks, $\bar{Y}^\cdot_{X^\cdot}$ is a disjoint union of $\bar{Y}^\cdot_{X^\cdot} = \bar{Y}^\cdot_{X^\cdot}$ ranging over all $D \in \mathbb{N}^D$ such...
that $g_X(D) = \hat{\lambda}$ (see §5.4). Choose $D \in \mathbb{N}^d$ such that the closure of $Y^\lambda_X$, in $\tilde{Y}^\lambda_X$ intersects the stratum $\tilde{Y}^\lambda_X$. The map
\begin{equation}
 Y^\lambda_X, \rightarrow \tilde{Y}^\lambda_X
\end{equation}
is proper because $\tilde{Y}^D_X, \tilde{Y}^\lambda_X$ are proper over $A^D_X, A^\lambda_X$, respectively, and the natural map $A^D_X, \rightarrow A^\lambda_X$ is proper. Therefore the closure of $\tilde{Y}^0_X$, in $\tilde{Y}^\lambda_X$ is contained in the image of (5.15). Note that the stratification of $M_{X'}$ is indexed by $\tilde{\Theta}' \in \text{Sym}^\infty(\mathbb{C}_X, -0)$. In particular, $\tilde{\Theta}' \geq 0$ since $\mathbb{C}_X = \mathbb{N}^d$. Therefore $\tilde{Y}^0_X$ is a union of $\tilde{Y}^D_X, \times_{M_{X'}} M^\Theta_X$ for $\tilde{\Theta}' \geq 0$, which implies its image in $\tilde{Y}^\lambda_X$ is contained in the union of $\tilde{Y}^\lambda_X \times_{M_{X'}} M^\Theta_X$ for $\tilde{\Theta} \geq 0$.

Proof of Proposition 5.6.1. By Theorem 5.1.1(i), the closure of $M^\Theta_X$ is equal to the image of $\tilde{X}^\Theta \times_{\tilde{C}^\Theta, \tilde{\Theta}}$, so we will consider the latter. Note that $C^\Theta$ is stratified by disjoint loci $\tilde{C}^{\Theta'}$ for all partitions $\tilde{\Theta}'$ such that $\tilde{\Theta}$ refines $\tilde{\Theta}'$. By the description of the fibers of $Gr^\Theta_{G,C^\Theta} \rightarrow C^\Theta$ in (5.3), we have an identification
\begin{equation}
 \tilde{C}^{\Theta'} = \tilde{C}^{\Theta''}
\end{equation}
of reduced schemes. Therefore, replacing $\tilde{\Theta}$ by $\tilde{\Theta}'$, it suffices to show that the image of $\tilde{X}^\Theta \times_{\tilde{C}^\Theta, \tilde{\Theta}}$ contains $M^{\Theta'}$ if and only if $\tilde{\Theta}' \geq \tilde{\Theta}$.

The “only if” direction follows from the description of $\text{act}_v$ on $k$-points and Lemmas 5.2.4 and 5.6.2.

We will show the “if” direction only in the case when $\tilde{\Theta} = [\tilde{\theta}]$, $\tilde{\Theta}' = [\tilde{\theta}']$ are singleton (so $\tilde{\theta}' \geq \tilde{\theta}$) to lessen notation (allowing $\tilde{\theta} = 0$), but the multi-point version is proved in exactly the same way. Fix $v \in [C]$. We have a distinguished point in $\tilde{M}^{\Theta'}_X$ degenerate at $v$: the image under $\text{act}_v$ of $\tilde{\theta}' \in Y^{\tilde{\theta}', \tilde{\theta}}$. We will show that $\tilde{X}^\Theta \times_{\tilde{C}^\Theta, \tilde{\Theta}}$ contains this point. Then, stability of $\tilde{M}^{\Theta}_{X'}$ under generic-Hecke correspondences (Theorem 5.1.1(i) and Lemma A.4.6) and Proposition A.4.4 imply that $\tilde{M}^{\Theta}_{X'}$ contains all of $\tilde{M}^{\Theta'}_{X'}$.

Since $\tilde{\theta}' \geq \tilde{\theta}$, we can decompose $\tilde{\theta}' - \tilde{\theta} = \sum_{j=1}^d \tilde{\nu}_j$ for (not necessarily distinct) $\tilde{\nu}_j$ equal to valuations of colors $D_j \in D$ (in case $D_j$ is not uniquely determined by its valuation, the choice of $D_j$ is arbitrary). The graded factorization property gives a map $\tilde{\mathcal{C}} : \tilde{Y}^{\tilde{\theta}, \tilde{\theta}} \times \prod_j Y^{D_j}_{\tilde{\nu}_j} \rightarrow \tilde{Y}^{\tilde{\theta}}$.

We claim that the image of $\tilde{\mathcal{C}}$ contains $C = \tilde{Y}^{\tilde{\theta}, \tilde{\theta}}_{\text{red}}$ in its closure. (Note that $\tilde{\mathcal{C}}_{\text{red}} = \tilde{\mathcal{C}}^{d+1}$.) This will produce an irreducible variety whose generic point maps to $\tilde{M}^{\Theta}_{X'}$ while a special point maps to $\text{act}_v(t^{\tilde{\theta}}) \in \tilde{M}^{\Theta}_{X'}$.

Consider the Beilinson–Drinfeld affine Grassmannian $Gr_{T,C^{d+1}}$, whose fiber over $d + 1$ pairwise distinct points $(v_0, \ldots, v_d) \in \tilde{C}^{d+1}$ is $\prod_j Gr_B$ while the fiber over $v_0 = \ldots = v_d$ is $Gr_B$.

By Lemma 4.3.2, we have an isomorphism $Y^{\lambda} \cong Gr^\lambda_B \times_{\text{X}/L^+L+B(L^+X/L^+B)}$, which depends on a fixed base point $x_0 \in X$. Now a reduction to $G_{m} \backslash GL_2$ (see proof of Lemma 5.4.2 and Example 4.3.3) shows that the central fiber $Y^{\lambda} = \text{pt}$ is contained in $L^+N \cdot t^{\tilde{\theta}} \subset Gr^\lambda_B$. Therefore $\tilde{\mathcal{C}}$ is contained in the orbit of the multi-point jet space $(L^+N)_{C^{d+1}}$ acting on the closed subscheme $C^{d+1} \subset Gr_{T,C^{d+1}} \subset Gr_{B,C^{d+1}}$ given by $(v_0, \ldots, v_d) \mapsto t^{\tilde{\theta}} \prod_j t^{\tilde{\nu}_j}_j$, where the $v_j$'s are allowed to collide. The orbit of $(v_0, \ldots, v_d) \in \tilde{C}^{d+1}$ is
\begin{equation}
 \{t^{\tilde{\theta}}_v \times \prod_{j=1}^d (L^+N \cdot t^{\tilde{\nu}_j}_j) \subset Gr^\theta_B, v_0 \times \prod_{j=1}^d Gr^\nu_{v,j},
\end{equation}
while the orbit of the diagonal \( v = v_0 = \ldots = v_d \) is \( \mathbb{L}^+ N \cdot t_{v_i}^\theta = \{ t_{v_i}^\theta \} \subset \text{Gr}_{B,v} \) since \( \tilde{\theta} \) is antidominant.

Now assume that \( C = \mathbb{A}^1 \), which is justified by Proposition 4.2.3. Then we can identify \((\mathcal{L}^+ N)_C = \mathbb{L}^+ N \times C \). Let \( Y^{D_j}_X \) correspond to the point \( n_j t^\theta_j \in \text{Gr}_B \) for \( n_j \in \mathbb{L}^+ N(k) \). For any pairwise distinct \( v_0, \ldots, v_d \in \mathbb{A}^1 \) we have a line \( \mathbb{A}^1 \to C^{d+1} : a \mapsto (av_0, \ldots, av_d) \) contracting all points to 0. Multiplication defines a map \( m : (\mathbb{L}^+ N \times C)^d \to (\mathcal{L}^+ N)_C \). Letting \( m(n_1, \ldots, n_d) \) act on the point \( t^\theta_0 \prod_j t^\theta_j \in \text{Gr}_{T,C^{d+1}} \) as \( a \to 0 \), we get a curve connecting \( \{ t^\theta_0 \} \times \prod Y^{D_j}_X, v_j \to t^\theta_0 \). Hence the closure of \( \tilde{c} \) in \( \mathcal{Y}^\theta C^{d+1} \subset \text{Gr}_{B,C^{d+1}} \) contains \( \bar{\psi}_{\text{red}}^{\theta,\theta'} \). Since the map \( C^{d+1} \to A^{\theta} \) is finite and \( \tilde{c} \) is irreducible, we have proved the claim. \( \square \)

Now we draw some corollaries from Proposition 5.6.1.

**Corollary 5.6.3.** The open substack \( \mathcal{M}_X^\emptyset = \text{Bun}_H \) is dense in \( \mathcal{M}_{X,\text{can}} \) iff \( \mathcal{C}_X \cap \mathcal{V} = \mathcal{C}_{X,\text{can}} \).

This is an analog of [BG02, Proposition 1.2.3], which says that \( \text{Bun}_B \) is dense in \( \text{Bun}_B \) if \( [G, G] \) is simply connected.

**Proof.** Indeed, \( \mathcal{C}_X \cap \mathcal{V} = \mathcal{C}_{X,\text{can}} \) is precisely the condition that every \( \Theta \in \text{Sym}^\infty(\mathcal{C}_X - 0) \) is \( \geq 0 \). \( \square \)

Define \( D_{\text{sat}}^G(X) \) to be the set of primitive elements in \( \text{Prim}(\mathcal{C}_X) \) that cannot be decomposed as a sum \( \theta + \lambda \) where \( \theta, \lambda \) are both nonzero, \( \theta \in \mathcal{C}_X \) and \( \lambda \geq 0 \) (see §3.1.4 for the definition of primitive). Note that \( D_{\text{sat}}^G(X) \) contains \( D(X)(D(X) - D) \), the valuations of the \( G \)-stable divisors, but the containment may be strict.

**Corollary 5.6.4.** There is a bijection between the set of irreducible components of \( \mathcal{M}_X \) and

\[ \pi_1(H) \times \text{Sym}^\infty(D_{\text{sat}}^G(X)), \]

such that \( \hat{\mu} \in \pi_1(H), \hat{\Theta} \in \text{Sym}^\infty(D_{\text{sat}}^G(X)) \) corresponds to \( \hat{\mu} \mathcal{M}_X^\Theta \).

**Proof.** For any \( \hat{\Theta}' \in \text{Sym}^\infty(\mathcal{C}_X - 0) \), let \( \hat{\Theta}' \in \text{Sym}^\infty(\mathcal{C}_X - 0) \) be a minimal element with respect to the ordering \( \preceq \) such that \( \hat{\Theta}' \preceq \hat{\Theta}' \). Then \( \hat{\Theta}' \) can be refined to an element \( \hat{\Theta} \in \text{Sym}^\infty(D_{\text{sat}}^G(X)) \). Therefore the closure relations from Proposition 5.6.1 tell us that any stratum is contained in the closure of \( \mathcal{M}_X^\emptyset \) for a partition \( \Theta \) as above. By definition if \( \theta_1, \theta_2 \in D_{\text{sat}}^G(X) \) satisfy \( \theta_1 \geq \theta_2 \) then they must be equal. From this one deduces that \( \mathcal{M}_X^\emptyset \) is not contained in the closure of any other stratum.

Thus the closure of each \( \mathcal{M}_X^\emptyset, \hat{\Theta} \in \text{Sym}^\infty(D_{\text{sat}}^G(X)) \), is a union of irreducible components, and no irreducible component is contained in two different such closures. The Corollary now follows from the description of irreducible components of \( \mathcal{M}_X^\emptyset \) by Corollary 5.5.9. \( \square \)

**Lemma 5.6.5.** Let \( X_1 \to X_2 \) be a \( G \)-equivariant map of affine spherical varieties with \( X_1^\bullet = X_2^\bullet = H \setminus G \). Then the induced map \( X_1 \to X_2 \) is a closed embedding.

**Proof.** Let \( S \) be a test scheme and let \( (\mathcal{P}_G, \sigma_2) \in \mathcal{M}_{X_2}(S) \), where \( \sigma_2 : C \times S \to X_2 \times^G \mathcal{P}_G \) is a section. By Corollary 3.5.2 there exists a \( B \)-structure \( \mathcal{P}_B \) on \( \mathcal{P}_G \) after a suitable surjective étale base change \( S' \to S \) such that \( (\mathcal{P}_B, \sigma_2) \in \mathcal{Y}_{X_1}(S') \). Then in particular there exists a relative effective divisor \( D \subset C \times S' \) such that \( \sigma_2(C \times S' - D) \subset X_2 \times^B \mathcal{P}_B \), cf. §3.7.1. Since \( X_1^\bullet = X_2^\bullet \), we have \( X_1^\emptyset = X_2^\emptyset \). By Lemma 3.7.3 the condition that \( \sigma_2|_{C \times S' - D} \) extends to a section \( C \times S' \to X_1 \times^B \mathcal{P}_B = X_1 \times^G \mathcal{P}_G \) is closed in \( S' \). Therefore \( S' \times_{\mathcal{M}_{X_2}} \mathcal{M}_{X_1} \to S' \) is a closed embedding. \( \square \)
Lemma 5.6.5 implies that \( M_{\lambda} \) is a closed substack of \( M_X \) containing \( M^0_X \), and when the condition of Corollary 5.6.3 is satisfied, \( M_{\lambda} = M^0_X \).

5.7. Closure relations and components in the Zavava model. In order to extend the above results to strata of \( Y \), we will need the following result:

**Lemma 5.7.1.** Let \( y \in Y^{\lambda}(k) \) for \( \lambda \in \xi_X \). For any simple root \( \alpha \) with \( D(\alpha) = \{ D^+_\alpha, D^-_\alpha \} \) and any \( N \gg 0 \), there exists a \( k \)-point

\[
y' \in Y^{\lambda} \times C^{(N)} \times C^{(N)} \subseteq Y^{\lambda} \times Y^{N\nu_+^\alpha} \times Y^{N\nu_-^\alpha}
\]

such that the first coordinate is \( y \) and the image of \( y' \) under the composition

\[
y^{\lambda} \times Y^{N\nu_+^\alpha} \times Y^{N\nu_-^\alpha} \to Y^{\lambda + N\tilde{\alpha}} \to M_X
\]

coincides with the image of \( y \).

Above we are using the fact, from Lemma 5.4.2, that \( Y^{N\nu_+^\alpha} \) contains \( C^{(N)} \) if \( \nu_+^\alpha \neq \nu_-^\alpha \) or \( C^{(N)} \sqcup C^{(N)} \) if \( \nu_+^\alpha = \nu_-^\alpha \). In the latter case, Lemma 5.7.1 is picking out one of these components (depending on the point \( y \)).

**Proof.** The point \( y \) is equivalent to a datum \( (\mathcal{P}_B, \sigma) \) where \( \mathcal{P}_B \) is a \( B \)-bundle on \( C \) and \( \sigma : C \to X \times B \mathcal{P}_B \) is a section. Let \( \mathcal{P}_G = G \times_B \mathcal{P}_B \) denote the induced \( G \)-bundle. The image of \( y \) in \( M_X \) corresponds to \( (\mathcal{P}_G, \sigma) \). Set \( k := k(C) \). Then \( \sigma|_{Spec_k} \) defines a trivialization of \( \mathcal{P}_G|_{Spec_k} \), which we fix. With respect to this trivialization, \( B \)-structures on \( \mathcal{P}_G \) are in bijection with sections \( Spec_k \to \mathcal{P}_G \), and \( \mathcal{P}_B \) corresponds to \( 1 \in (G/B)(k) \). The preimage of \( (\mathcal{P}_G, \sigma) \) in \( Y \) identifies with the orbit \( H(\mathbb{A}) \cdot 1 \subseteq (G/B)(k) \). Since \( X^o P_{\alpha} / R(P_{\alpha}) = \mathbb{G}_m \setminus PGL_2 \), the orbit of \( H \cap P_{\alpha} \) on \( 1 \in P_{\alpha}/B = \mathbb{P}^1 \) is \( \mathbb{G}_m \). Let \( r \in \mathbb{G}_m(k) = k(C)^* \) be a rational function on the curve \( C \). Then the principal divisor defined by \( r \) is of the form \( \nu_+^\alpha - \nu_-^\alpha \) where \( \nu_\pm^\alpha \) are effective divisors with disjoint supports. By the Riemann–Roch theorem, for any \( N \gg 0 \) there exists \( r \in k(C)^* \) such that \( \deg(\nu_+^\alpha) = \deg(\nu_-^\alpha) = N \) and the supports of \( \nu_+^\alpha \) and \( \nu_-^\alpha \) are both contained in \( \sigma^{-1}(X^o \times B \mathcal{P}_B) \). Under the isomorphism \( X^o \mathcal{P}_B \cong \mathbb{G}_m \setminus \mathbb{P}^1 \), let us identify \( D^+_\alpha \) with \( 0 \in \mathbb{P}^1 \) and \( D^-_\alpha \) with \( \infty \in \mathbb{P}^1 \). Then the preimage of \( (\mathcal{P}_G, \sigma) \) in \( Y \) corresponding to \( r \in \mathbb{P}^1(k) \) has the desired property.

Recall from Corollary 5.5.9 that the irreducible components of \( M^\Theta_X \) are denoted by \( \hat{\mu} M^\Theta_X \), with \( \hat{\mu} \in \pi_1(H) \). For any \( \hat{\lambda} \in \xi_X \), define \( \hat{\mu} Y^{\lambda, \hat{\Theta}} := Y^{\lambda} \times_{M_X} \hat{\mu} M^\Theta_X \) and \( \hat{\mu} Y^{\lambda, \hat{\Theta}} := Y^{\lambda} \times_{M_X} \hat{\mu} M^\Theta_X \).

**Corollary 5.7.2.** For any \( \hat{\lambda} \in \xi_X \), \( \hat{\mu} \in \pi_1(H) \), \( \hat{\Theta} \in \text{Sym}^\infty(\xi_X^\infty - 0) \), the scheme \( \hat{\mu} Y^{\lambda, \hat{\Theta}} \) is irreducible (if nonempty), and \( \hat{\mu} Y^{\lambda, \hat{\Theta}} \) is open dense in it.

**Proof.** For \( \hat{\lambda} \) large enough, the claim immediately follows from Corollaries 3.5.2 and 5.6.4. Now, for arbitrary \( \hat{\lambda} \), consider \( \hat{\lambda}' = \hat{\lambda} + \sum_{n \in \Delta \infty} n_{\alpha} \hat{\alpha} \) large enough. By the graded factorization property and Lemma 5.7.1, there exists an étale map

\[
\hat{\mu} Y^{\hat{\lambda}, \hat{\Theta}} \times C \to \hat{\mu} Y^{\hat{\lambda}, \hat{\Theta}},
\]

where \( C = \prod_{n \in \Delta \infty} C^{(n)} \times C^{(n)} \).

By the validity of the proposition for large \( \hat{\lambda} \), we know that \( \hat{\mu} Y^{\hat{\lambda}, \hat{\Theta}} \) is connected and dense in \( \hat{\mu} Y^{\hat{\lambda}, \hat{\Theta}} \). Therefore if \( \hat{\mu} Y^{\hat{\lambda}, \hat{\Theta}} \) is not irreducible, there exist \( y_1, y_2 \) in disjoint connected components of \( \hat{\mu} Y^{\hat{\lambda}, \hat{\Theta}} \) and \( c_1, c_2 \in C \) such that \( (y_1, c_1) \) and \( (y_2, c_2) \) have the same image in \( \hat{\mu} Y^{\hat{\lambda}, \hat{\Theta}} \). From the definition of the factorization map \( (5.16) \), we deduce that this can only happen if \( y_1, y_2 \) belong to the image of another factorization map \( \hat{\mu}' Y^{\hat{\lambda}, \hat{\Theta}} \times C' \to \hat{\mu} Y^{\lambda, \hat{\Theta}} \) for some \( \hat{\mu}' \in \pi_1(H) \), \( 0 < \hat{\nu} \leq \hat{\lambda}' - \lambda \) and irreducible \( C' \). We are done by induction on \( \hat{\lambda} \).
Corollary 5.7.3. For every $\lambda \in \epsilon_X$, there is an injection from the set of irreducible components of $Y^\lambda$ to $\pi_1(H) \times \text{Sym}^\infty(D^G_{\text{sat}}(X))$.

Proof. By Corollary 5.7.2, the irreducible components $Y^\lambda$ are those $\mu Y^\lambda \supseteq \Theta$ that are nonempty, for $\Theta \in \text{Sym}^\infty(\epsilon_X, -1)$ minimal in the $\geq$ order.

In §6.2, and in particular Corollary 6.2.2, we will see a different description of the irreducible components of $Y_X$, based on the partition of $Y_X \cdot = Y^0_X$ into the subschemes $Y^0_X$ of §5.4.

5.8. Proof of Theorem 5.1.5. For $\Theta \in \text{Sym}^\infty(\epsilon_X, -1)$, let $P_{L^+G}(\text{Gr}_{G,C}^\Theta)$ denote the category of perverse sheaves on $\text{Gr}_{G,C}^\Theta$ that are equivariant with respect to the action of $(L^+G)^{\Theta(i)}$, considered as a group scheme over $\text{Sym}C$ (defined in §A.1). For $F \in P(M_X)$ and $G \in P_{L^+G}(\text{Gr}_{G,C}^\Theta)$, we can form the twisted external product

\[ \mathcal{F} \boxtimes G \in P(M_X \times \text{Gr}_{G,C}^\Theta) \]

with respect to the projections of $\text{Gr}_{G,C}^\Theta$ to $M_X$ and $L^+G \setminus \text{Gr}_{G,C}^\Theta$. Then we define the external convolution product by

\[ \mathcal{F} \ast G := \text{act}_{M,!}(\mathcal{F} \boxtimes G) \in D^b_c(M_X). \]

We have introduced all the ingredients in the statement of Theorem 5.1.5. The remainder of this section will be devoted to its proof.

Observe that $\mathcal{I} \mathcal{C}_{M_X} \boxtimes IC_{\text{Gr}_{G,C}^\Theta} = \text{IC}_{M_X \times \text{Gr}_{G,C}^\Theta}$, which we will simply denote $\mathcal{I} \mathcal{C}$ for brevity. We have a stratification

\[ M_X^0 \times \text{Gr}_{G,C}^\Theta = \bigcup_{\Theta', \Theta''} \tilde{M}_{\Theta'} \times \text{Gr}_{G,C}^{\Theta''} \]

running over all $\Theta' \supseteq 0$ and $\Theta'' \supseteq \Theta_1$ where $\Theta$ refines $\Theta_1$ (the definition of $\Theta'' \supseteq \Theta_1$ is analogous to that of $\supseteq$). Lemma 5.5.3(i) implies that $\text{act}_{M,!}(\mathcal{I} \mathcal{C})$ is contained in the dense open stratum corresponding to $\Theta' = 0$ and $\Theta'' = \Theta$.

5.8.1. By Proposition 3.1.7 we know that $\text{IC}_{M_X}$ is constructible with respect to the fine stratification of $M_X$. Therefore $\mathcal{I} \mathcal{C}$ is constructible with respect to the stratification above, so if we let $L^\Theta_{\text{glob}}$ denote the $!$-restriction of $\mathcal{I} \mathcal{C}$ to the stratum $M^\Theta_{X} \times \text{Gr}_{G,C}^{\Theta''}$, we have that its cohomology sheaves are local systems. Since $L^\Theta_{\text{glob}}$ is the restriction of an IC complex, it lives in perverse cohomological degrees $\leq 0$, and the inequality is strict unless $\Theta' = 0$ and $\Theta'' = \Theta$. Since its cohomology sheaves are local systems, this implies that $L^\Theta_{\text{glob}}$ lives in usual cohomological degrees $\leq -\dim(M^\Theta_{X} \times \text{Gr}_{G,C}^{\Theta''})$, and the inequality is strict unless $\Theta' = 0$ and $\Theta'' = \Theta$. We are abusing notation here: $M^\Theta_{X}$ may not be connected, in which case each connected component should be considered separately.

We abuse notation and also use $L^\Theta_{\text{glob}}$ to denote its $!$-extension to $M_X \times \text{Gr}_{G,C}^\Theta$. Then by the characterizing properties of the intermediate extension (and the fact that $\mathcal{I} \mathcal{C}$ is Verdier self-dual), Theorem 5.1.5 is equivalent to the following assertion:

Proposition 5.8.2. For $\Theta', \Theta''$ as above, consider the complex $\text{act}_{M,!}(L^\Theta_{\text{glob}})$. Then:

(i) It lives in $pD^\leq(-1)(M_X)$ unless $\Theta' = 0$ and $\Theta'' = \Theta$.  

Proof. By Corollary 5.8.1, the irreducible components $Y^\lambda$ are those $\mu Y^\lambda \supseteq \Theta$ that are nonempty, for $\Theta \in \text{Sym}^\infty(\epsilon_X, -1)$ minimal in the $\geq$ order.

In §6.2, and in particular Corollary 6.2.2, we will see a different description of the irreducible components of $Y_X$, based on the partition of $Y_X \cdot = Y^0_X$ into the subschemes $Y^0_X$ of §5.4.
(ii) The $\ast$-restriction of $\text{act}_X(L^0_{\text{glob}})$ to $\overline{M}_X - M_X^\Theta$ lives in perverse cohomological degrees $\leq -1$.

(iii) There is a natural identification $\text{act}_X(L^0_{\text{glob}})|_{M_X^\Theta}^\ast \cong \text{IC}_{M_X^\Theta}$.

Recall from (5.9) that $\text{act}_C$ factors into

$$M_X \times \text{Gr}_{G,C} \overset{\text{act}}{\longrightarrow} M_X \times C \overset{\text{pr}_1}{\longrightarrow} M_X.$$  

Let $\overline{M}_{C,\Theta}$ denote the image of $\text{act}_{C,\Theta}$, which is a closed subscheme of $M_X \times C^\Theta$. Then $\text{pr}_1$ induces a map $\overline{M}_{C,\Theta} \to \overline{M}_X$ which is finite because the fiber over $f : C \to X/G$ consists of divisors $(D^\Theta)^\Theta$ such that the support of each $D^\Theta$ is contained in the degenerate locus $C - f^{-1}(X^\bullet/G)$. Moreover $\text{pr}_1$ restricts to identity on $\overline{M}_X^\Theta$.

Therefore it suffices to prove Proposition 5.8.2 with $\text{act}_X$ replaced by $\text{act}_{C,\Theta}$. To simplify notation we only present the proof in the case when $\Theta = [\hat{\theta}]$ is singleton. The general case is proved in the same way by considering multiple points on $C$ simultaneously.

Now we have $C^{[\hat{\theta}]} = C$ and $\tilde{\Theta}'' = [\tilde{\eta}]$ for $\tilde{\eta} \in -\tilde{\lambda}_G^\circ$ such that $\tilde{\eta} \geq \tilde{\theta}$. Fix a point $v \in |C|$ and consider the fiber of $\text{act}_C : \overline{M}_X \times \text{Gr}_{G,C} \to M_X \times C$ over $v$.

5.8.3. By Corollary 3.5.2, it suffices to prove Proposition 5.8.2 after base change to the Zastava model, i.e., we pullback along the diagram (5.10) for all $\tilde{\lambda}$ large enough. The corresponding diagram for strata is given by (5.11). We $\ast$-pullback with a shift by the fiber dimension of $Y^\lambda \to M_X$ so that $\text{IC}_{M_X^\lambda \times \text{Gr}_{G,v}}$ goes to $\text{IC}_{Y^\lambda \times \lambda}$. With this shift, the discussion of §5.8.1 implies that $L^0_{\text{glob}}$ goes to a complex

$$L_{\text{flag}}^{\lambda,\tilde{\lambda},\tilde{\theta},\tilde{\eta}} \in D^b(Z^\lambda_v \times \tilde{\lambda},\tilde{\theta},\tilde{\eta}),$$

which lives in usual cohomological degrees $\leq -\dim(Z^\lambda_v \times \tilde{\lambda},\tilde{\theta},\tilde{\eta}) - 1$, and the inequality is strict unless $\tilde{\Theta}' = 0$ and $\tilde{\eta} = \tilde{\theta}$ (the extra $-1$ is due to the fact that we restricted along $v \to C$).

Recall from Proposition 5.5.5 that $Z^\lambda_v \times \tilde{\lambda},\tilde{\theta},\tilde{\eta}$ has a stratification by $Z^\lambda_v \times \tilde{\lambda},\tilde{\theta},\tilde{\eta}$ where $\tilde{v}$ runs through the weights of $V^\tilde{\theta}$. Let $L_{\text{flag}}^{\lambda,\tilde{v},\tilde{\lambda},\tilde{\theta}}$ denote the $\ast$-restriction of $L_{\text{flag}}^{\lambda,\tilde{v},\tilde{\lambda},\tilde{\theta}}$ to the corresponding stratum. We also abuse notation and use $L_{\text{flag}}^{\lambda,\tilde{v},\tilde{\lambda},\tilde{\theta}}$ to denote its $!$-extension to $Z^\lambda_v \times \tilde{\lambda}$. The key observation we will use is that:

- $L_{\text{flag}}^{\lambda,\tilde{v},\tilde{\lambda},\tilde{\theta}}$ lives in usual cohomological degrees $\leq -\dim(Z^\lambda_v \times \tilde{\lambda},\tilde{\theta},\tilde{\eta}) - 1$, which is independent of $\tilde{v}$, and the inequality is strict unless $\tilde{\Theta}' = 0$ and $\tilde{\eta} = \tilde{\theta}$.

In the case $\tilde{\Theta}' = 0$ and $\tilde{\eta} = \tilde{\theta}$, it is easy to deduce from Lemma 5.5.7 that

$$\text{act}_{\tilde{\eta}}((L_{\text{flag}}^{\lambda,\tilde{v},\tilde{\lambda},\tilde{\theta}})^\ast)_{|y^{\lambda,\tilde{v},\tilde{\lambda},\tilde{\theta}}} \cong \text{IC}_{y^{\lambda,\tilde{v},\tilde{\lambda},\tilde{\theta}}} \cong \text{IC}_{y^{\lambda,\tilde{v},\tilde{\lambda},\tilde{\theta}} \times Y^\lambda \times \lambda}$$

where $y^{\lambda,\tilde{v},\tilde{\lambda},\tilde{\theta}} \times Y^\lambda \times \lambda$ is a dense open subscheme of both $y^{\lambda,\tilde{v},\tilde{\lambda},\tilde{\theta}}$ and $Z^\lambda_v \times \tilde{\lambda},\tilde{v},\tilde{\lambda},\tilde{\theta} \times C$.

Now consider the restriction of $\text{act}_{\tilde{\eta}}$ to

$$Z^\lambda_v \times \tilde{\lambda},\tilde{v},\tilde{\theta} \cong y^{\lambda,\tilde{v},\tilde{\lambda},\tilde{\theta}} \times (\tilde{S}^\lambda \cap \text{Gr}_{G,v}) \to y^{\lambda,\tilde{v},\tilde{\lambda},\tilde{\theta}}.$$ 

Any fiber of the above map embeds into $S^\lambda \cap \text{Gr}_{G,v}$, which has dimension $\langle \rho_G, \tilde{v} - \tilde{\eta} \rangle$. Therefore to prove Proposition 5.8.2 it is enough, by the very definition of the perverse t-structure, to prove the following:
Lemma 5.8.4. Let $\Theta', \tilde{\eta}, \tilde{\lambda}, \tilde{\nu}$ be as above. Then we have

$$-\dim(Z_v^{\tilde{\lambda},\tilde{\Theta}',\tilde{\eta}}) + 2\langle \rho_G, \tilde{\nu} - \tilde{\eta} \rangle \leq -\dim \text{act}_y(Z_v^{\lambda - \nu, \tilde{\lambda}, \tilde{\Theta}', \tilde{\eta}}).$$

Note that the statement of the lemma has nothing to do with $\tilde{\theta}$.

5.8.5. Dimension inequalities. Recall that if $\tilde{\Theta}' = \sum_{\tilde{\theta}'} N_{\tilde{\theta}'}[\tilde{\theta}']$ is a formal sum, we use $\deg(\tilde{\Theta}')$ to denote $\sum_{\tilde{\theta}'} N_{\tilde{\theta}'}[\tilde{\theta}'] \in \mathbb{C}$ and $|\tilde{\Theta}'| := \sum_{\tilde{\theta}'} N_{\tilde{\theta}'}$. One can deduce a multi-point version of Corollary 5.5.6, which says that there is an isomorphism $\mathcal{Y}^\deg(\tilde{\Theta}'), \tilde{\Theta}' \cong \tilde{\Theta}'$. Then using the graded factorization property, we get an open embedding

$$y^\lambda - \nu, \tilde{\lambda}, \tilde{\Theta}' \times \mathcal{C}^{\tilde{\Theta}'} = y^\lambda - \nu, \tilde{\lambda}, \tilde{\Theta}' \hookrightarrow y^\lambda - \nu, \tilde{\Theta}'',$$

which is dense by (a multi-point version of) Lemma 5.5.7. By avoiding the fixed point $v$, we get open dense embeddings

$$y^\lambda - \nu, \tilde{\lambda}, \tilde{\Theta}' \times (S^v \cap \text{Gr}_{G,v}) \hookrightarrow Z_v^{\lambda - \nu, \tilde{\lambda}, \tilde{\Theta}', \tilde{\eta}}.$$

Hence $y^\lambda - \nu, \tilde{\lambda}, \tilde{\Theta}' \times (S^v \cap \text{Gr}_{G,v})$ is an open dense subscheme of $Z_v^{\lambda - \nu, \tilde{\lambda}, \tilde{\Theta}', \tilde{\eta}}$ and its image under $\text{act}_y$ is contained in

$$y^\lambda - \nu, \tilde{\lambda}, \tilde{\Theta}' \times \mathcal{Y}_v \subset y^\lambda,$$

where $\mathcal{Y}_v$ denotes the central fiber of $\mathcal{Y}$ over $v$. We deduce the inequality

(5.17) \[ \dim \text{act}_y(Z_v^{\lambda - \nu, \tilde{\lambda}, \tilde{\Theta}', \tilde{\eta}}) \leq \dim(y^\lambda - \nu, \tilde{\Theta}' + [\tilde{\eta}]) + \dim(\mathcal{Y}_v^\rho). \]

Consider the formal sum $\tilde{\Theta}' + [\tilde{\eta}]$ as a partition. Then Theorem 5.1.1 implies that $\text{act}_M$ is a birational map from $M_{X}^{\tilde{\Theta}'} \times \text{Gr}_{G,C}^{\tilde{\eta}}$ to the closure of $X^{\tilde{\Theta}' + [\tilde{\eta}]}$. Therefore \( \dim(Z_v^{\lambda - \nu, \tilde{\lambda}, \tilde{\Theta}', \tilde{\eta}} \times C) = \dim(y^\lambda - \nu, \tilde{\Theta}' + [\tilde{\eta}]) \). From the previous paragraph we know that

$$y^\lambda - \nu, \tilde{\lambda}, \tilde{\Theta}' \times C = y^\lambda - \nu, \tilde{\Theta}' + [\tilde{\eta}],$$

is open dense. We conclude that

(5.18) \[ \dim(Z_v^{\lambda - \nu, \tilde{\Theta}'}, \tilde{\eta}) = \dim(y^\lambda - \nu, \tilde{\Theta}' + [\tilde{\eta}]). \]

Combining (5.17) and (5.18), to prove Lemma 5.8.4 it suffices to show that

(5.19) \[ \dim(y^\lambda - \nu, \tilde{\Theta}', \tilde{\eta}) + 2\langle \rho_G, \tilde{\nu} - \tilde{\eta} \rangle \leq \dim(y^\lambda - \nu, \tilde{\Theta}' + [\tilde{\eta}]) + \dim(\mathcal{Y}_v^\rho). \]

This inequality now has nothing to do with $\tilde{\Theta}'$, so we might as well set $\tilde{\Theta}' = 0$. Observe that since $\tilde{\nu} \geq \tilde{\eta}$, we have $\dim(y^\nu - \nu, \tilde{\Theta}' + [\tilde{\eta}]) \leq 2\langle \rho_G, \tilde{\nu} - \tilde{\eta} \rangle$ by Lemma 5.4.2. Then the graded factorization property gives an étale map $y^\lambda - \nu, \tilde{\Theta}' \times y^\nu - \nu, \tilde{\Theta}' \rightarrow y^\lambda - \nu, \tilde{\Theta}'$, so we have the even stronger inequality

$$\dim(y^\lambda - \nu, \tilde{\Theta}') + 2\langle \rho_G, \tilde{\nu} - \tilde{\eta} \rangle \leq \dim(y^\lambda - \nu, \tilde{\Theta}')$$

This completes the proof of Lemma 5.8.4 and hence the proof of Theorem 5.1.5.

6. Stratified semi-smallness

We keep the assumptions of §5, i.e., $B$ acts simply transitively on $X^\circ$ and every simple root of $G$ is a spherical root of type $T$.

The main result of this section is the following, which will be proved in §6.3.

Theorem 6.0.1. Under the assumptions above, $\pi_!(\mathbb{IC}_{\mathcal{Y}})$ is perverse and constructible with respect to the stratification $\mathcal{A}^\lambda = \bigcup_{\deg(\mathfrak{A}) = \lambda} \mathcal{C}^\mathfrak{A}$ from Proposition 3.2.3.
6.1. Upper bounds on dimension. Define
\[ Y^{\hat{\lambda}, \hat{\theta}} = Y^\hat{\lambda} \times \overline{M}^\hat{\theta}_X \subset Y^\hat{\lambda} \]
\[ Y^{\hat{\lambda}, \hat{\theta}} = Y^{\hat{\lambda}, \hat{\theta}} \cap Y^\hat{\lambda} \subset S^\hat{\lambda} \]
and let \( Y^{\hat{\lambda}, \hat{\theta}}, Y^{\hat{\lambda}, \hat{\theta}} \) denote the corresponding intersections with \( Y^\hat{\lambda} \) (the notation is justified by Proposition 5.6.1). From the stratification \( Y^\hat{\lambda} = \bigcup \nu Y^\lambda \) we deduce that
\[ Y^{\hat{\lambda}, \hat{\theta}} = \bigcup_{\hat{\lambda}' \leq \hat{\lambda}} Y^{\hat{\lambda}', \hat{\theta}}. \]

Proposition 6.1.1. Let \( \hat{\lambda} \in c_X - 0 \) and \( \hat{\theta} \in c_{\hat{X}}. \) For any connected component \( \mathcal{Y} \) of \( Y^{\hat{\lambda}, \hat{\theta}}, \) we have
\[ \dim(\mathcal{Y} \cap \mathcal{Y}) \leq \frac{1}{2}(\dim(\mathcal{Y}) - 1). \]

Moreover, whenever the above inequality is an equality for an irreducible component \( \mathcal{Y} \) of \( Y^{\hat{\lambda} \cap \mathcal{Y}}, \) the same holds for the inequality of Proposition 4.4.2; that is, the closure \( \overline{Y} \) in the affine Grassmannian meets a semi-infinite orbit \( S^{\hat{\lambda}} \) with \( \langle \rho_G, \hat{\lambda} - \hat{\lambda} \rangle = \dim(\overline{Y}). \)

Proof. Let \( \overline{\mathcal{Y}} \) denote the closure of \( \mathcal{Y} \) in \( Y^{\hat{\lambda}}. \) Recall from Corollary 5.7.2 that the connected components of \( Y^{\hat{\lambda}, \theta} \) are of the form \( \hat{\mu} Y^{\hat{\lambda}, \theta} \) for \( \hat{\mu} \in \pi_1(\hat{H}). \) So \( \mathcal{Y} = \hat{\mu} Y^{\lambda, \theta} \) for some \( \hat{\mu} \in \pi_1(\hat{H}), \) and \( \overline{\mathcal{Y}} \subset Y^{\hat{\lambda}} \times \overline{M}^{\hat{\theta}}_X, \) where \( \overline{M}^{\hat{\theta}}_X \) is the corresponding irreducible component of \( \overline{M}^{\hat{\theta}}_X. \)

Fix an irreducible component \( \mathcal{Y} \) of \( Y^{\hat{\lambda} \cap \mathcal{Y}}, \) and let \( \overline{\mathcal{Y}} \) be its closure in \( Y^{\hat{\lambda}} \cap \mathcal{Y}. \) From Proposition 4.4.2 we know, by intersecting \( Y \) with semi-infinite orbits in the affine Grassmannian, that there is a \( \hat{\lambda}' \leq \hat{\lambda} \) with \( \mathcal{Y}' := \overline{\mathcal{Y}} \cap S^{\hat{\lambda}'} \) nonempty of dimension zero, and \( d := \dim \mathcal{Y} \leq \langle \rho_G, \hat{\lambda} - \hat{\lambda}' \rangle. \) By the closure relations of Proposition 5.6.1, \( \mathcal{Y}' \) is contained in the central fiber of \( \hat{\mu} Y^{\hat{\lambda}, \theta} \) for some \( \hat{\theta} \geq \hat{\theta}. \)

Since \( \hat{\lambda} - \hat{\lambda}' \in \hat{\lambda}^{\text{pos}}_G, \) we can decompose \( \hat{\lambda} - \hat{\lambda}' = \sum_{\alpha \in \Delta_G} n_\alpha (\hat{\mu} D^+_\alpha + \hat{\nu} D^-_\alpha) \) where the sum is over simple roots and \( \sum n_\alpha = \langle \rho_G, \hat{\lambda} - \hat{\lambda}' \rangle. \) By the graded factorization property and Lemma 5.7.1, there is an étale map
\[ \hat{\mu} Y^{\hat{\lambda}, \hat{\theta}'} \times \prod_{\alpha \in \Delta_G} \left( C^{(n_\alpha)} \times C^{(n_\alpha)} \right) \to \hat{\mu} Y^{\hat{\lambda}, \hat{\theta}'} \]
over \( \hat{\mu} M^{\hat{\theta}}_X. \) Observe that \( \mu Y^{\hat{\lambda}, \hat{\theta}'} \subset \nu Y^{\hat{\lambda}, \hat{\theta}} \subset \overline{Y} \) by Corollary 5.7.2.

If \( \hat{\lambda}' \neq 0, \) then \( \hat{\mu} Y^{\hat{\lambda}, \hat{\theta}'} \) contains \( \mathcal{Y}' \times C \) and hence (6.2) implies that \( \dim(\mathcal{Y}) \geq 1 + 2\langle \rho_G, \hat{\lambda} - \hat{\lambda}' \rangle. \)

Therefore
\[ d \leq \langle \rho_G, \hat{\lambda} - \hat{\lambda}' \rangle \leq \frac{1}{2}(\dim(\mathcal{Y}) - 1) \]
if \( \hat{\lambda}' \neq 0. \) This proves the claim in the case \( \hat{\lambda}' \neq 0. \)

There remains to consider when \( d = \langle \rho_G, \hat{\lambda} - \hat{\lambda}' \rangle \) and \( \hat{\lambda}' = 0. \) In this case, again by Proposition 4.4.2, there is a simple root \( \alpha \) such that \( Y \cap S^\alpha = Y^{\alpha, 0} \) has dimension 1. By Lemma 6.1.2 below, \( \dim(Y^{\alpha, 0}) = 0, \) so we have a contradiction. \( \square \)

Lemma 6.1.2. If \( \alpha \) is simple root of \( G, \) then \( \dim(Y^{\alpha, 0}) = 0. \)
Proof. Let \( y \in Y(\pi) \) be a \( k \)-point. Then \( y : C \to X/B \) is a map such that \( y(C - v) = \text{pt.} \) Let \( f_\alpha \in \pi(X)(B) \) denote a nonzero \( B \)-eigenfunction with eigenvalue \( \alpha \). Since \( (\alpha, \tilde{\alpha}) = 2 \), we deduce that \( y(v) \in (X/B)(k) \) lifts to a point in the vanishing locus of \( f_\alpha \). On the other hand, \( (\alpha, \tilde{\nu}_D) = v_D(f_\alpha) \leq 0 \) for all \( D \in D(X) - D(\alpha) \). Therefore \( y \) factors through \( C \to (X - \bigcup_{D \in D(X) - D(\alpha)} D)/B \). Hence \( y \) must belong to the central fiber of \( Y_{\pi} \), for some \( D \in \pi(NB) \), with \( g_X(D) = \alpha \). By Lemma 5.4.2, we see that the central fiber of \( Y_{\pi} \) is empty unless \( \nu^+_\alpha = \tilde{\nu}^{-\alpha} = 1/2 \) and \( D = 2D_\alpha^+ \), in which case the central fiber is a point.

6.2. Connected components of open Zastava. Recall from \( \S 5.4 \) that \( Y_{\pi}^0 = Y_{\pi} \) is a disjoint union of subschemes \( Y_{\pi}^D \), indexed by \( D \in \pi(NB) \), i.e., multisets of colors. Therefore we have a map \( \pi_0(Y_{\pi} X) \to \pi_0(NB) \). On the other hand, Corollary 5.7.3 gives an injection \( \pi_0(Y_{\pi} X) \hookrightarrow \pi_1(H) \times \epsilon_X \) where \( \nu\nu_{Y_{\pi} X} \hookrightarrow (\tilde{\mu}, \tilde{\lambda}) \) when the former is nonempty.

Observe that \( \pi_1(H) \otimes \mathbb{Q} \cong \chi(H) \otimes \mathbb{Q} \). Then tensoring (5.5) by \( \mathbb{Q} \), we get an injection

\[
\bigoplus \mathbb{Q} \hookrightarrow \bigoplus (\pi_1(H) \times \hat{\lambda}_X) \otimes \mathbb{Q}.
\]

One can check that the above maps fit into a commutative diagram

\[
\begin{array}{c}
\pi_0(Y_{\pi} X) \\
\downarrow \ \\
\pi_1(H) \times \epsilon_X
\end{array}

\begin{array}{c}
\pi_0(Y_{\pi} X) \\
\downarrow \ \\
\pi_1(H) \times \epsilon_X
\end{array}
\]

which automatically implies the left vertical arrow is injective. We now show that it is in fact a bijection.

Lemma 6.2.1. For \( D \in \pi(NB) \), the smooth scheme \( Y_{\pi}^D \) is connected of dimension \( \text{len}(D) \).

Proof. As discussed in \( \S 5.4 \), we may assume that \( X = X_{\text{can}} \) and \( \epsilon_X = \pi(NB) \). Now the claim is equivalent to showing that, under those assumptions, \( Y_{\pi}^X \) is connected for \( \tilde{\lambda} = \sum n_D \tilde{\nu}_D \). One deduces from the graded factorization property of \( Y \) that if \( Y_{\pi}^X \) is not connected, there must exist a possibly different \( \tilde{\lambda} \) with a connected component \( \mathcal{Y} \) contained entirely in the preimage of the diagonal \( Y_{\pi}^X \times \tilde{\lambda} \). Then \( \dim(\mathcal{Y} \cap \mathcal{Y}) = \dim \mathcal{Y} - 1 \), and the dimension inequality of Proposition 6.1.1 can only hold if \( \dim \mathcal{Y} = 1 \). By Corollary 5.7.2, the component \( \mathcal{Y} \) must be of the form

\[
\mathcal{Y} = \mu Y_{\pi}^\lambda \times \text{Bun}_C^\tilde{\lambda}
\]

for some \( \mu \in \pi_1(H) \). Now by the graded factorization property and Lemma 5.7.1, we have an étale map

\[

\mu Y_{\pi}^\lambda \times \prod_{\alpha \in \Delta_C} C(N_\alpha) \times C(N_\alpha) \to \mu Y_{\pi}^\lambda
\]

for \( \tilde{\lambda} = \lambda + \sum N_\alpha \alpha \) and any \( N_\alpha \) large enough. Thus \( \dim \mu Y_{\pi}^\lambda = 1 + 2 \sum N_\alpha \). By Lemma 3.5.1 we may assume that \( \text{Bun}_C^\tilde{\lambda} \to \text{Bun}_G^\tilde{\lambda} \) is smooth. Note that \( \dim \text{Bun}_C^\tilde{\lambda} \) only depends on the image of \( \tilde{\mu} \) in \( \pi_1(H) \). On the other hand, the commutative diagram (6.5) says that this image is determined by \( \tilde{\lambda} \). These observations imply that \( \mu Y_{\pi}^\lambda = \text{Bun}_C^\tilde{\lambda} \times \text{Bun}_G^\tilde{\lambda} \) is equidimensional. However we know that \( \mu Y_{\pi}^\lambda \) has a connected component birational to \( A^{\tilde{\lambda}} \), which is of dimension \( \sum n_D \tilde{\nu} + 2 \sum N_\alpha \). The equality

\[
\dim \mu Y_{\pi}^\lambda = 1 + 2 \sum N_\alpha = \sum n_D \tilde{\nu} + 2 \sum N_\alpha
\]
forces $\lambda = \tilde{\nu}D$, for some color $D' \in D$, hence $D = D'$. Lemma 5.4.2 now implies that $\mathcal{Y}^{\nu,D,0}$ is connected.

**Corollary 6.2.2.** For every $\lambda \in \mathcal{C}_X$, $\tilde{\theta} \in \mathcal{C}_X^-$, the connected components of $\mathcal{Y}^{\lambda,\tilde{\theta}}$ are in bijection with the closures of

$$\mathcal{Y}_{X^+}^{\nu,D} \times \mathcal{Y}^{\tilde{\theta},\hat{\theta}} \hookrightarrow \mathcal{Y}^{\lambda,\hat{\theta}}$$

for $D \in \mathbb{N}^P$ such that $g_X(D) = \lambda - \tilde{\theta}$.

**Proof.** Immediate from Lemmas 5.5.7(i) and 6.2.1. \qed

### 6.3. Stratified semi-smallness

Following [MV07, §4], we will use the notion of a stratified semi-small map, which we now review. Let $f : Y \to A$ be a proper map between two stratified spaces $(Y,S)$ and $(A,B)$. Suppose all strata are smooth and connected and each $f(S), S \in S$ is a union of strata $B \in \mathcal{B}$. We say $f$ is étale-locally trivial (in the stratified sense) if whenever $B \subset f(S)$, the restriction of $f$ to $S \cap f^{-1}(B) \to B$ is étale-locally a trivial fibration. We say that $f$ is stratified semi-small if it is étale-locally trivial and for any $S \in \mathcal{S}$ and any $B \in \mathcal{B}$ such that $B \subset f(S)$ we have

$$\dim(f^{-1}(a) \cap S) \leq \frac{1}{2}(\dim S - \dim B)$$

for any (and thus all) $a \in B$.

The notion of stratified semi-smallness is relevant due to the observation below, which follows from dimension counting and the definition of the perverse $t$-structure:

**Lemma 6.3.1 ([MV07, Lemma 4.3]).** If $f$ is a stratified semi-small map then $f_* (\mathcal{F}) \in \mathcal{P}_S(A)$ for all $\mathcal{F} \in \mathcal{P}_S(Y)$.

Note that the lemma holds even if the stratifications are not Whitney. In this case we simply define $\mathcal{P}_S(Y) := \mathcal{P}(Y) \cap D^b_S(Y)$ to be the subcategory of perverse sheaves that are $S$-constructible, i.e., the $\mathcal{F} \in \mathcal{P}(Y)$ such that $H^i(\mathcal{F})|_S$ is a local system of finite rank for all $i \in \mathbb{Z}$ and $S \in \mathcal{S}$.

### 6.3.2. Let us return to our situation: consider the proper map $\tilde{\pi} : \mathcal{Y}^\lambda \to \mathcal{A}^\lambda$. We have the smooth stratification defined in Proposition 4.2.1,

$$\mathcal{Y}^\lambda = \bigcup_{\nu,\hat{\theta}} \mathcal{Y}^{\lambda,\hat{\theta}}, \quad \nu \mathcal{Y}^{\lambda,\hat{\theta}} \cong C_\nu \times \mathcal{Y}^{\lambda-\nu,\hat{\theta}}$$

for $\nu \in \mathcal{A}_G^{\text{pos}}$, $\hat{\Theta} \in \text{Sym}^\infty(\mathcal{C}_X - 0)$. Let $(\mathcal{Y}^\lambda, \mathcal{S})$ denote the stratification by the connected components of $\nu \mathcal{Y}^{\lambda,\hat{\theta}}$. We will not show that $\mathcal{S}$ is a Whitney stratification; for our purposes the following suffices\(^{18}\).

**Lemma 6.3.3.** For any $\lambda \in \mathcal{C}_X$, the IC complex of $\mathcal{Y}^\lambda$ is $\mathcal{S}$-constructible, i.e.,

$$\text{IC}_{\mathcal{Y}^\lambda} \in \mathcal{P}_S(\mathcal{Y}^\lambda).$$

**Proof.** Let $\nu \in \mathcal{A}_G^{\text{pos}}$ be such that $\mathcal{Y}^\lambda = \leq \nu \mathcal{Y}^\lambda$, which exists since $\mathcal{Y}^\lambda$ is of finite type. For any $\mu \in \mathcal{A}_G^{\text{pos}}$ large enough, we have a smooth correspondence preserving stratifications

$$\mathcal{Y}^\lambda \leftarrow \mathcal{Y}^{\lambda,\mu} \times \mathcal{Y}^{\nu,0} \rightarrow \leq \nu \mathcal{Y}^{\lambda+\mu + \nu} =: Y$$

---

\(^{18}\)This result can be proved independent of the characteristic of $k$ using the argument of §A.4.7 and generic-Hecke equivariant sheaves, as defined in [GN10, §2.3].
Theorem 6.3.4. \( P \) for (6.7) 
\[
\mathcal{F} \mathcal{I} \mathcal{M}_X \cong \left( \mathcal{I} \mathcal{C}_{\mathcal{M}_G} \boxtimes \mathcal{I} \mathcal{C}_{\text{Bun}_G} \right) \mid_{Y}.
\]
Now Proposition 3.1.7 implies that \( \mathcal{I} \mathcal{C}_{\mathcal{M}_X} \) is constructible with respect to the fine stratification on \( \mathcal{M}_X \), and Lemma 4.5.6 implies that \( \mathcal{I} \mathcal{C}_{\text{Bun}_G} \) is constructible with respect to the stratification by defect. Thus it follows that \( \mathcal{I} \mathcal{C}_Y \) is constructible.

Proof. Fix \( \pi \in \mathcal{S} = \text{Sym}^\infty(\epsilon_X - 0) \) such that \( \deg(\mathcal{S}) = \lambda \).

Now Theorem 6.0.1 follows from Lemmas 6.3.1, 6.3.3 and the following theorem:

**Theorem 6.3.4.** The map \( \bar{\pi} : (\mathcal{Y}^\lambda, \mathcal{S}) \to (\mathcal{A}^\lambda, \mathcal{B}) \) is stratified semi-small.

Proof. Fix \( \mathcal{S} \in \text{Sym}^\infty(\epsilon_X - 0) \) such that \( \bar{\lambda} = \deg(\mathcal{S}) \). Let \( I = \{1, \ldots, |\mathcal{S}|\} \) be the finite set of cardinality \( |\mathcal{S}| \). We fix an ordering \( \mathcal{S} = \sum_{i \in I}[\lambda_i] \) on our partition \( \mathcal{S} \), so each \( \lambda_i \in \epsilon_X \). Let \( \mathcal{C}^I \) denote the I-fold product \( \mathcal{C}^I \) with the diagonal divisor removed. Then the map \( \mathcal{C}^I \to \mathcal{C}^\mathcal{S} \) corresponds to choosing an ordering on an unordered multiset of points in \( C \).

Now fix \( \nu \in \mathcal{A}_G^\mathcal{S} \), \( \nu \in \text{Sym}^\infty(\epsilon_X - 0) \). Observe that the restriction \( \mathcal{C} : \mathcal{C} \times \mathcal{A}^\lambda \to \mathcal{A}^\lambda \) factors through \( \mathcal{C} \times \mathcal{A}^\lambda \to A_\nu^\lambda \times \mathcal{A}^\lambda \to \mathcal{A}^\lambda \). Restricting the latter composition to \( \mathcal{C} \to \mathcal{C} \mathcal{S} \to \mathcal{A}^\lambda \) along the base gives a disjoint union

\[
(C_{\nu} \times \mathcal{A}^\lambda) \times \mathcal{C}^I \cong \bigsqcup_{\nu_1, \lambda_1} \mathcal{C}^I
\]

over assignments \( i \in I \mapsto \nu_i \in \mathcal{A}_G^\mathcal{S} \), \( \lambda_i \in \epsilon_X \) such that \( \nu_i + \lambda_i = \bar{\lambda}_i \), and \( \mathcal{C}^I \) embeds as a connected component of the left-hand side through the composition

\[
\mathcal{C}^I \to \prod_{i \in I} (C_{\nu_i} \times \mathcal{A}^\lambda_i) \to C_{\nu} \times \mathcal{A}^\lambda \mathcal{S},
\]

where each copy of \( C \) embeds diagonally in the first arrow and the second arrow is the product of the graded factorization maps for \( C_{\nu} \) and \( \mathcal{A}^\lambda \). (Note that both \( \nu_1 \) and \( \lambda_1 \) are allowed to be 0.)

The fiber product \( \mathcal{Y}^\lambda \times \mathcal{A}^\lambda, \mathcal{S}, \mathcal{B} \) over the component \( \mathcal{C}^I \) corresponding to a fixed \( \nu_1, \lambda_1 \) is isomorphic to \( \prod_{i \in I}(Y_{\nu_i}^{\lambda_i} \times C) \). This maps to \( (\mathcal{L}^+ X)^{I} \to \prod (L^X \times C) \), which has a stratification by \( \prod (L^X \times C) \) over all assignments \( i \mapsto \theta_i \in \epsilon_X \) (including zero). Let \( \Theta_0 = \hat{\Theta} + (|I| - |[\Theta]|)|0| \in \text{Sym}^\infty(\epsilon_X) \) denote the multiset with zero satisfying \( |\Theta_0| = |I| \). Then the preimage of \( \mathcal{L}_{\hat{\Theta}}^X \) under \( (\mathcal{L}^+ X)^{I} \to (\mathcal{L}^+ X)^{\hat{\Theta}} \) is the disjoint union of \( \prod (L^X \times C) \) for all \( (\theta_i)_{i \in I} \) such that \( \Theta_0 = \sum_i [\theta_i] \) as a formal sum (cf. §A.2 for notation). By definition, the fiber product \( \mathcal{Y}^\lambda, \mathcal{S}, \mathcal{B} \) over the component \( \mathcal{C}^I \) is the preimage of \( (\mathcal{L}^+ X)^{\hat{\Theta}} \), and we conclude that

\[
\mathcal{Y}^\lambda, \mathcal{S}, \mathcal{B} \to \mathcal{C}^I \cong \bigsqcup_{\nu_1, \lambda_1} \prod_{i \in I}(Y_{\nu_i}^{\lambda_i}, \theta_i \times C)
\]

where \( i \mapsto \nu_i, \lambda_i, \theta_i \) are as above.
Since $\hat{\mathcal{C}}^l \to \hat{C}^\Psi$ is finite étale, we deduce that $\overline{\pi}(S), S \in \mathcal{S}$ is a union of strata, and (since everything is of finite type) the restriction of $\overline{\pi}$ to $\nu Y^\lambda, \hat{\Theta} \cap \overline{\pi}^{-1}(\hat{C}^\Psi) \to \hat{C}^\Psi$ is étale-locally a trivial fibration.

It remains to check the dimension inequality (6.6). Let $\mathcal{Q}, \nu, \hat{\Theta}$ be as before, and fix a connected component $S$ of $\nu Y^\lambda, \hat{\Theta}$. We deduce from (6.7) that for any $a \in \hat{C}^\Psi$, the restricted fiber $\overline{\pi}^{-1}(a) \cap S$ is contained in a union of $\prod_i (Y_{\lambda', \hat{\Theta}_i} \cap S_i)$ for $\nu_i, \lambda_i', \hat{\Theta}_i$ as above and $S_i$ some connected component of $\nu Y_{\lambda', \hat{\Theta}_i}$. By Proposition 6.1.1, we have

$$\dim(Y_{\lambda', \hat{\Theta}_i} \cap S_i) \leq \frac{1}{2}(\dim(S_i) - 1). \tag{6.8}$$

The image of the composition

$$\prod_{i \in I}^\circ (\nu_i, S_i) \to \prod_{i \in I}^\circ \nu Y_{\lambda', \hat{\Theta}_i} \to \nu Y^\lambda, \hat{\Theta}$$

is connected, so it must be contained in $S$. Thus $\dim(S) \geq \langle \rho_G, \nu \rangle + \sum_i \dim(S_i)$. Summing (6.8) over $I$, we get

$$\dim(\pi^{-1}(a) \cap S) \leq \frac{1}{2}(\dim(S) - \dim(C^\Psi) - \langle \rho_G, \nu \rangle),$$

which establishes the inequality (6.6). \hfill \Box

### 6.4. Euler product.

Let us explain how we can combine the graded factorization property of $\hat{\mathcal{Y}}$ with Theorem 6.3.4 to deduce that $\overline{\pi}!(IC^\xi_{\mathcal{Y}})$ “looks like an Euler product”.

In the expression that we are about to obtain, a special role will be played by those strata $Y^\lambda, \hat{\Theta}$ of $\nu Y^\lambda$ which correspond to elements $\hat{\Theta} \in D^\xi_{\text{aff}}(X) \cup \{0\}$. Recall, by Corollary 5.7.2, that the closures of those strata are unions of irreducible components of $Y$. Let

$$\mathcal{B}_{X, \lambda} = \bigcup_{\hat{\Theta} \in D^\xi_{\text{aff}}(X) \cup \{0\}} \bigcup_{\mathcal{Y}} \mathcal{B}_{\mathcal{Y}}, \tag{6.9}$$

where $\mathcal{Y}$ runs over all irreducible components of $Y^\lambda, \hat{\Theta}$, and $\mathcal{B}_{\mathcal{Y}}$ is the set of those irreducible components $\mathcal{B}$ of the central fiber $Y^\lambda \cap \mathcal{Y}$ for which the inequality of (6.1) is an equality, that is,

$$\dim \mathcal{B} = \frac{1}{2}(\dim \mathcal{Y} - 1). \tag{6.10}$$

Such components will be said to be of critical dimension; we will explicate this dimension in Proposition 6.5.1. The sets $\mathcal{B}_{X, \lambda}$ will define the crystal of $X$ in Section 7. For now, we treat them as a black box.

We let $V_{X, \lambda}$ denote the free vector space on $\mathcal{B}_{X, \lambda}$, that is,

$$V_{X, \lambda} = \bigoplus_{\mathcal{B}_{X, \lambda}} \mathcal{B}_{X, \lambda}. \tag{6.11}$$

Note that, when $X$ is defined over a finite field $\mathbb{F}$, and $k$ is its algebraic closure, the (geometric) Frobenius morphism induces a dimension-preserving bijection between the sets $\mathcal{B}_{X, \lambda}$ and $\mathcal{B}_{X, k\lambda}$, for every $\lambda \in \hat{\Lambda}$. Hence, $Fr^r$ acts naturally on the sum of vector spaces $\bigoplus_{\lambda \in \hat{\Lambda}} V_{X, \lambda}$.

For a partition $\mathfrak{A} = \sum_{\mu \in \mathfrak{A} - 0} N_{\mu} [\mu] \in \text{Sym}^\infty(\mathcal{C} - 0)$, let $t^\mathfrak{A} : \hat{\mathcal{C}}^\mathfrak{A} := \prod \hat{\mathcal{C}}(N_{\mu}) \hookrightarrow \mathcal{A}^\lambda$ denote the locally closed embedding. This extends to a finite map $\hat{t}^\mathfrak{A} : C^\mathfrak{A} := \prod C(N_{\mu}) \to \mathcal{A}^\lambda$ which is the normalization of the closure of $\hat{\mathcal{C}}^\mathfrak{A}$ in $\mathcal{A}^\lambda$. 

Proposition 6.4.1. For $\lambda \in \zeta_X$, there exists a canonical isomorphism

\[ \tilde{\pi}_t(|C|) = \bigoplus_{\deg(\mathcal{R}) = \lambda} \left( \bigotimes \text{Sym}^N_{|\mathcal{R}|}(V_{X,\bar{\mu}}) \right) \otimes \bar{\iota}_\mathcal{R}^! (\mathcal{IC}_{C^{\mathcal{R}}}) \]

where $\mathcal{R} = \sum_{\mu \in \zeta_X} N_{\mu}[\bar{\mu}]$ and the spaces $V_{X,\bar{\mu}}$ are defined by (6.11).

When $X$ is defined over a finite field $\mathbb{F}$, and $k$ is its algebraic closure, this isomorphism is Galois-equivariant.

The implied Galois action on the right hand side of (6.12) is the one obtained by the action of Frobenius on the sum of spaces $V_{X,\bar{\mu}}$ (by permuting their basis elements), and the standard Weil structure $\overline{\mathbb{Q}}_l(\frac{\mathcal{R}}{2})[[\mathcal{R}]]$ on $\mathcal{IC}_{C^{\mathcal{R}}}$.

Note that if $\mathcal{R} = [\lambda]$ is the trivial partition, then $C[\lambda] = C$ and $i^{[\lambda]} : C \to A^{\lambda}$ is the diagonal embedding. The corresponding summand of $\tilde{\pi}_t(|C|)$ above is $V_{X,\lambda} \otimes \mathcal{IC}_C$. We call this the diagonal contribution of $\tilde{\pi}_t(|C|)$.

Proof. The proof follows the same logic as [BFGM02, §5.4, 5.11]. Theorem 6.0.1 implies that $\tilde{\pi}_t(|C|)$ is perverse, and the decomposition theorem ([BBDG18, Théorème 6.2.5]) implies that it is semisimple. Since $\tilde{\pi}_t(|C|)$ is constructible with respect to the stratification by $i^{\mathcal{R}} : C^{\mathcal{R}} \to A^{\lambda}$ for $\mathcal{R} \in \text{Sym}^\infty(\zeta_X - 0)$, $\deg(\mathcal{R}) = \lambda$, we deduce that there exists a canonical decomposition

\[ \tilde{\pi}_t(|C|) = \bigoplus_{\deg(\mathcal{R}) = \lambda} i^\mathcal{R}_! (\mathcal{L}_\mathcal{R})[[\mathcal{R}]] \]

where $i^\mathcal{R}_!$ denote the middle extension functor along the locally closed embedding, and $\mathcal{L}_\mathcal{R}$ is a local system on $C^{\mathcal{R}}$.

Now consider the trivial partition $[\lambda]$. For $v \in |C|$ let $\delta^{\lambda}_v : v \to A^{\lambda}$ denote the composition of $v \to C$ with $\delta^{\lambda} : C \to A^{\lambda}$. Recall from §4.3.4 that $\mathcal{Y}^{\lambda}_v \times_{A^{\lambda},\delta^{\lambda}} C \cong \mathcal{Y}^{\lambda} \times_{\text{Aut} C^{\mathcal{R}}} C^{\lambda}$. Taking the $*$-pullback along $\delta^{\lambda}_v$ of (6.13), we have

\[ R^! \mathcal{Y}^{\lambda}_v \mathcal{IC}_{\mathcal{Y}^{\lambda}_v} \cong \bigoplus_{\deg(\mathcal{R}) = \lambda} (\delta^{\lambda}_v)^* i^\mathcal{R}_! (\mathcal{L}_\mathcal{R})[[\mathcal{R}]]. \]

For $\mathcal{R} = [\lambda]$, we have $\mathcal{L}_\mathcal{R}[\lambda]$ is a local system on $C$, so $(\delta^{\lambda}_v)^* i^\mathcal{R}_! (\mathcal{L}_\mathcal{R})[\lambda]_t$ lives in cohomological degree $-1$. For $\mathcal{R} \neq [\lambda]$, we have $\dim C^{\mathcal{R}} > 1$ so the uniqueness property of middle extension implies that $(\delta^{\lambda}_v)^* i^\mathcal{R}_! (\mathcal{L}_\mathcal{R})[[\mathcal{R}]]$ has lisse cohomology sheaves on $C$ and lives in usual cohomological degrees $< -1$. Therefore we deduce that

\[ \mathcal{L}_\mathcal{R}[\lambda]_t \cong H^{-1}_c (\mathcal{Y}^{\lambda}_v, \mathcal{IC}_{\mathcal{Y}^{\lambda}_v}), \]

which is the top cohomological degree.

Recall from Corollary 5.7.3 that the irreducible components of $\mathcal{Y}^{\mu}_{t}$ are naturally parametrized by a subset of $\pi_1(H) \times \text{Sym}^\infty(D^G_{\text{nat}}(X))$. Let $\mathcal{Y}^{\lambda,\Theta}$ denote the union of $\mathcal{Y}^{\lambda,\Theta}$ for all $\Theta \in \text{Sym}^\infty(D^G_{\text{nat}}(X))$. Then $\mathcal{Y}^{\lambda,\Theta}$ is a disjoint union of smooth connected components with the irreducible components of $\mathcal{Y}^{\lambda}$, by Corollary 5.7.2. Again, the uniqueness property of the IC complex implies that $\mathcal{IC}_{\mathcal{Y}^{\lambda}}|_{\mathcal{Y}^{\lambda}-\mathcal{Y}^{\lambda,\Theta}}$ lives in strictly negative perverse cohomological degrees.

Since $\tilde{\pi}_t$ is perverse $t$-exact by Theorem 6.3.4, we deduce that $\tilde{\pi}_t(|C|)|_{\mathcal{Y}^{\lambda}-\mathcal{Y}^{\lambda,\Theta}}$ is constructible and lives in strictly negative perverse degrees. This in turn implies that $(\delta^{\lambda}_v)^* \tilde{\pi}_t(|C|)|_{\mathcal{Y}^{\lambda}-\mathcal{Y}^{\lambda,\Theta}}$
lives in (usual=perverse) degrees $< -1$. We conclude that
\[ \mathcal{L}^\lambda|_{v \to C} = H_c^{-\ell}(\mathcal{Y}, (\text{IC}_{\mathcal{P}^\lambda}(\mathcal{Y}, \mathcal{Y}))|_{\mathcal{Y}_\lambda}) = \bigoplus_{\mathcal{Y}} H_c^{\dim \mathcal{Y} - 1}(\mathcal{Y} \cap \mathcal{Y}, \mathcal{T}_\ell(\mathcal{H}^{\dim \mathcal{Y}})), \]
with the sum running over all irreducible components of $\mathcal{Y}_\lambda$. Note that $\mathcal{Y}_\lambda \cap \mathcal{Y}_\lambda$ is empty unless $Y = \{Y\}$ is singleton, for $Y \in D^b_{\text{sat}}(X) \cup \{0\}$. Moreover, the right hand side consists of only top cohomological degrees, by Proposition 6.5.1, so $H_c^{\dim \mathcal{Y} - 1}(\mathcal{Y} \cap \mathcal{Y}, \mathcal{T}_\ell(\mathcal{H}^{\dim \mathcal{Y}}))$ is equal to the sum
\[ \bigoplus_{\mathcal{Y}} \mathcal{T}_\ell(\frac{1}{2}), \]
where $\mathcal{B}_{\mathcal{Y}}$ is the set of irreducible components of $\mathcal{Y} \cap \mathcal{Y}$ of dimension $\frac{\dim \mathcal{Y} - 1}{2}$. In particular, $\mathcal{L}^\lambda|_{v \to C}$ has trivial monodromy under $\text{Aut}_k[[t]]$, so we deduce that $\mathcal{L}^\lambda \cong V_{X, \lambda} \otimes \text{IC}_{C}$ where $V_{X, \lambda}$ is defined by (6.11) (with the $(\frac{1}{2})$-twist absorbed by $\text{IC}_{C}$).

Next, consider an arbitrary partition $\mathcal{R} = \sum_{\mu \in \mathcal{R}} N_\mu[\bar{\mu}]$. We defined $\tilde{\mathcal{C}}^\mathcal{R} = \prod_{\mu} \mathcal{C}(N_\mu)$. By the graded factorization property, we have a diagram with Cartesian squares
\[ \begin{array}{cccc}
\prod_{\mu} (\mathcal{Y} \times C) & \longrightarrow & \prod_{\mu} (\mathcal{Y}) & \longrightarrow \\
\downarrow & & \downarrow & \\
\prod \tilde{\mathcal{C}}(N_\mu) & \longrightarrow & \prod \tilde{\mathcal{C}}(A_{\mu}) & \longrightarrow \\
\end{array} \]
and the composition of the bottom arrows factors through the $(\prod \tilde{\mathcal{C}}(N_\mu))$-toral
\[ \prod \tilde{\mathcal{C}}(N_\mu) \to \prod \mathcal{C}(N_\mu) = \tilde{\mathcal{C}}^\mathcal{R}, \]
where $\mathcal{G}_N$ denotes the symmetric group on $N$ elements. By induction, we deduce that
\[ (6.14) \quad \mathcal{L}^\mathcal{R}|_{\prod \tilde{\mathcal{C}}(N_\mu)} \cong (\mathcal{G}(V_{X, \bar{\mu}} \otimes \text{IC}_{C})^{\mathcal{R}N_\mu})|_{\prod \tilde{\mathcal{C}}(N_\mu)}.
\]
There is a natural $\mathcal{G}_{N_\mu}$-equivariant structure on $(V_{X, \bar{\mu}} \otimes \text{IC}_{C})^{\mathcal{R}N_\mu}$ compatible with the $\mathcal{G}_{N_\mu}$-action on $C^{N_\mu}$. On the other hand, we have the map
\[ (\mathcal{Y} \times C)^{\times N_\mu} \to (\mathcal{Y} \times C)^{\times N_\mu} \times \tilde{\mathcal{C}}(N_\mu) \]
which is a $\mathcal{G}_{N_\mu}$-toral, where $\mathcal{G}_{N_\mu}$ acts on the left hand side in the natural way. Now from the definition of $V_{X, \bar{\mu}}$ we deduce that the isomorphism (6.14) must intertwine the $\prod \tilde{\mathcal{C}}(N_\mu)$-structures. By Galois descent we conclude that $\mathcal{L}^\mathcal{R} \cong (\mathcal{G}(V_{X, \bar{\mu}} \otimes \text{IC}_{C})^{\mathcal{R}N_\mu})|_{\prod \tilde{\mathcal{C}}(N_\mu)}$, since $\tilde{\mathcal{C}}^\mathcal{R} : \mathcal{C}(N_\mu) \to \mathcal{A}^{\lambda}$ is the normalization of the closure of the stratum $\mathcal{C}(N_\mu)$ in $\mathcal{A}^{\lambda}$, the middle extension of $\text{IC}_{C}(\mathcal{R})$ is isomorphic to $\tilde{\mathcal{C}}^\mathcal{R}(\text{IC}_{C}(\mathcal{R}))$.

When $X$ is defined over a finite field $\mathbb{F}$ and $k$ is the algebraic closure, the Galois group of $k$ over $\mathbb{F}$ acts naturally on the set of components $\mathcal{B}_X := \bigcup_{\mu \in \mathcal{R}} \mathcal{B}_X(\mu)$, and the above isomorphisms are clearly equivariant, taking into account that $\tilde{\mathcal{C}}^\mathcal{R}(\text{IC}_{C}(\mathcal{R}))$ is defined as $\tilde{\mathcal{C}}^\mathcal{R}(\text{IC}_{C}(\mathcal{R}))|_{\mathcal{R}}(\mathcal{R})$. \hfill $\square$

6.5. Critical dimension. We can now give a more precise description of the diagonal contribution $V_{X, \lambda}$ defined in (6.11), that is, the free vector space on the set $\mathcal{B}_X(\lambda)$ of components of critical dimension in the “open strata” of the central fiber $\mathcal{Y}_\lambda$.

Proposition 6.5.1. For $\lambda \in \mathcal{O}_X - 0$, the set $\mathcal{B}_X(\lambda)$ of components of critical dimension on the central fiber $\mathcal{Y}_\lambda$ consists of
(i) the irreducible components of $\mathcal{Y}_X^\bullet \cap \mathcal{Y}^\lambda$ of dimension $\frac{1}{2}(\text{len}(D) - 1)$, for $D \in \mathbb{N}^D$ with $g_X(D) = \check{\lambda}$;

(ii) the irreducible components of $S^\lambda \cap \text{Gr}_G^\check{\theta}$ of dimension $\langle \rho_G, \check{\lambda} - \check{\theta} \rangle$, for $\check{\theta} \in \mathcal{D}^{\text{sat}}(X)$, embedded in $\mathcal{Y}^\lambda$ via (5.14).

Remark 6.5.2. We have MV cycles for every $\check{\theta} \in \mathfrak{c}_X^\lambda$, but only those belonging to $\mathcal{D}^{\text{sat}}(X)$ contribute to $V_{X,\check{\lambda}}$ since those correspond to $\mathcal{Y}^\lambda$ which are connected components of $\mathcal{Y}_X^\lambda$. We will reserve the term critical dimension of $\mathcal{Y}^\lambda$ for the maximal dimensions in the two cases above.

Proof. By definition, an element of $\mathfrak{B}_X,\check{\lambda}$ is a component $b$ of the central fiber $\mathcal{Y}_X^\lambda \cap \mathfrak{Y}$, where $\mathfrak{Y}$ is an irreducible component of the smooth stratum $\mathcal{Y}^\check{\lambda,\check{\theta}}$, for some $\check{\theta} \in \mathcal{D}^{\text{sat}}(X) \cup \{0\}$, such that

$$\dim(b) = \frac{1}{2}(\dim(\mathfrak{Y}) - 1).$$

If $\check{\theta} = 0$, then $\mathcal{Y}^\check{\lambda,\check{\theta}}$ is the disjoint union of connected components $\mathcal{Y}_X^\bullet$ for $D \in \mathbb{N}^D$ with $g_X(D) = \check{\lambda}$, by Lemma 6.2.1. Then (6.15) becomes $\dim(b) = \frac{1}{2}(\text{len}(D) - 1)$.

If $\check{\theta} \neq 0$, by Corollary 6.2.2 the connected components of $\mathcal{Y}^\check{\lambda,\check{\theta}}$ are in bijection with the closures of

$$\mathcal{Y}_X^\bullet \times \mathcal{Y}^\check{\lambda,\check{\theta}} \hookrightarrow \mathcal{Y}^\check{\lambda,\check{\theta}}$$

for $D \in \mathbb{N}^D$ such that $g_X(D) = \check{\lambda} - \check{\theta}$. The statement now follows from the following lemma, which we write separately, for later use, because it applies to arbitrary $\check{\theta} \neq 0$.

Lemma 6.5.3. For any $\check{\theta} \in \mathfrak{c}_X^\lambda - 0$, $D \in \mathbb{N}^D$, denoting by $\mathfrak{Y}$ the closure of the image of

$$\mathcal{Y}_X^\bullet \times \mathcal{Y}^\check{\lambda,\check{\theta}} \hookrightarrow \mathcal{Y}^\check{\lambda,\check{\theta}}$$

we have $\dim(\mathcal{Y}^\check{\lambda} \cap \mathfrak{Y}) \leq \frac{1}{2}\text{len}(D) = \frac{1}{2}(\dim(\mathfrak{Y}) - 1)$. The irreducible components of $\mathcal{Y}^\check{\lambda,\check{\theta}}$ for which this is an equality are precisely the MV cycles in $S^\lambda \cap \overline{\text{Gr}_G^\check{\theta}}$ of dimension $\langle \rho_G, \check{\lambda} - \check{\theta} \rangle$, embedded in $\mathcal{Y}^\lambda$ via (5.14).

Proof. Proposition 6.1.1 implies that $\dim(\mathcal{Y}^\check{\lambda} \cap \mathfrak{Y}) \leq \frac{1}{2}(\dim(\mathfrak{Y}) - 1)$. Since $\check{\theta} \neq 0$, we have $\mathcal{Y}_X^\check{\lambda,\check{\theta}} = C$, and by Lemma 6.2.1 this inequality translates to $\dim(\mathcal{Y}^\check{\lambda} \cap \mathfrak{Y}) \leq \frac{1}{2}\text{len}(D)$.

If $v \in |C|$ is the point we are taking central fibers with respect to, then $\mathcal{Y}^\lambda$ maps to the substack $\mathfrak{M}_{X,\check{v}} \subset \mathfrak{M}_X$ of maps that are only $G$-degenerate at $v$. Recall from Theorem 5.1.1 that $\mathfrak{M}_{X,\check{v}}$ is contained in the image of

$$\text{act}_{\mathfrak{M}_{X,v}}: \text{Bun}_H \times \overline{\text{Gr}_G^\check{\theta}} \to \mathfrak{M}_{X,\check{v}}$$

and the map is birational onto its image. We deduce from (5.11) and Proposition 5.5.5 that the fiber product $(\text{Bun}_H \times \overline{\text{Gr}_G^\check{\theta}}) \times_{\mathfrak{M}_X} \mathcal{Y}^\check{\lambda}$ has a stratification by

$$\bigcup_{D} \mathcal{Y}^{\check{\lambda} - v,0} \times (S^\check{\lambda} \cap \text{Gr}_G^\check{\theta})$$

where $v$ ranges over the weights of $V^\check{\theta}$.

Observe that we have an embedding $\check{\lambda}^\text{pos}_G \hookrightarrow \mathbb{N}^D$ by sending a simple coroot $\check{\alpha} \mapsto D^+_\check{\alpha} + D^-_{\check{\alpha}}$. By restricting to $X^\check{v} P_{\check{\alpha}}$ we can deduce that the image of $\check{\alpha}$ in $\pi_1(H) \otimes \mathbb{Q}$ under (6.4) is zero.
Thus the commutativity of diagram (6.5) ensures that if we restrict to the connected component of \( \text{Bun}_H \) corresponding to \( \mathcal{Y}_X^B \), then the stratification above becomes

\[
\bigcup_{\nu} (\mathcal{Y}_X^{\bar{\nu}} \cap \mathcal{Y}_X^{D,\nu}(\mathcal{Y}_X^{\bar{\nu}})) \times (\mathcal{S}_G^\nu \cap \mathcal{G}_G^\nu),
\]

where \( \bar{\nu} - \bar{\theta} \in \mathcal{A}_G^{\text{pos}} \subset \mathbb{N}^D \). In particular, the dimension of the stratum corresponding to \( \bar{\nu} \) is

\[
\leq \frac{1}{2} \left( \text{len}(D - (\bar{\nu} - \bar{\theta})) - 1 \right) + \langle \rho_G, \bar{\nu} - \bar{\theta} \rangle \leq \frac{1}{2} \left( \text{len}(D) - 1 \right)
\]

by Proposition 6.1.1 unless \( D = \bar{v} - \bar{\theta} \). Thus in order for \( \dim \mathcal{Y}_X^{\bar{\lambda},\bar{\theta}} = \frac{1}{2} \text{len}(\bar{\lambda} - \bar{\theta}) \), we must have \( \bar{\lambda} = \bar{v} \) is a weight of \( V^\theta \) and \( \mathcal{Y}_X^{\bar{\lambda},\bar{\theta}} \) is birational to an irreducible component of \( \mathcal{C}_G^\lambda \), i.e., a Mirković–Vilonen cycle. By Lemma 5.5.11, this latter case always occurs. \( \square \)

**Remark 6.5.4.** By Proposition 6.5.1, the irreducible components of central Zastava fibers of critical dimension, which give rise to the “new” contributions \( V_{X,\bar{\lambda}} \) to the pushforward of the IC sheaf by Proposition 6.4.1, are of two different kinds: those associated to the Zastava space of the open \( G \)-orbit \( X^\bullet \), and those associated to certain strata of the affine Grassmannian. On the other hand, Theorem 5.1.5 gives a similar description of the intersection complex of the global model in terms of the Hecke action on the intersection complex of the global model for \( X^\bullet \). These two descriptions “match” under the nearby cycles functor of Theorem 8.3.6 and the Hecke action on Drinfeld’s compactification \( \text{Bun}_X^- \) (cf. [BG02]).

### 6.6. The case of finite fields.

When \( k \) is the algebraic closure of a finite field \( F \), and \( X \) is defined over \( F \), satisfying the assumptions of §2.1.3, the action of the geometric Frobenius \( \text{Fr} \) morphism on \( \tilde{\pi}_l(\text{IC}_X^{\bar{\lambda},\bar{\theta}}) \) is described, up to a yet unknown permutation action on the set \( \mathcal{B}_X^+ = \bigcup_{\bar{\lambda}} \mathcal{B}_{X,\bar{\lambda}} \) of central components of critical dimension, by Proposition 6.4.1. We use this to prove part of Theorem 1.1.2, and Theorem 1.1.4, from the introduction.

**Proof of Theorem 1.1.2.(i),(iv),(v) and Theorem 1.1.4.** Recall that \( \mathfrak{o} \), in the context of these theorems, denotes the ring \( \mathbb{F}[[t]] \), where \( \mathbb{F} \) is the finite field of definition of \( X \), and \( F \) is its fraction field.

We need to recall the definition of the IC function \( \Phi_0 \) from [BNS16]: It is a function on \( (X(\mathfrak{o}) \cap X^\bullet(F))/G(\mathfrak{o}) \) which, in our case, is parameterized by the set \( (c^\gamma_X)^{\text{Fr}} \) of elements of \( c^\gamma_X \) that are fixed under the Galois group. To define it, choose an arc \( \gamma \) in the coset of such an element \( \bar{\theta} \), and consider a finite-dimensional formal model \( Y_Y \) of the formal neighborhood of \( \gamma \) in the arc space \( L^X \) (Definition 3.8.1). In our case, we can take \( Y = \mathcal{Y}_X^{\bar{\theta}} \) and \( y = \text{the point} t^{\bar{\theta}} \) on the central fiber \( \mathcal{Y}_X^{\bar{\theta},\bar{\theta}} \), by Theorem 3.8.2. Then, the value of \( \Phi_0 \) on \( \bar{\theta} \) is equal to the trace of geometric Frobenius on the stalk of the intersection complex \( IC_Y \) at \( y \), where the intersection complex is normalized to be constant (without Tate or cohomological twists) on the smooth locus of \( Y \).

In our setting, this means that for every component \( \mathcal{V} \) as in Proposition 6.4.1, the Tate and cohomological twist on \( IC_{\mathcal{V}} \) should be modified from \( \mathcal{L}_\mathcal{V}(\dim \mathcal{V}) \) to \( \mathcal{L}_\mathcal{V} \), and (6.11) should be replaced by the space

\[
\bigoplus_{\mathcal{V}} \bigoplus_{\mathfrak{b} \in \mathcal{B}_{X,\bar{\lambda}}} \mathcal{L}_\mathcal{V}(-\dim \mathcal{V}/2)[-\dim \mathcal{V}] = \bigoplus_{\mathfrak{b} \in \mathcal{B}_{X,\bar{\lambda}}} \mathcal{L}_\mathcal{V}(-\dim \mathfrak{b} -1/2)[-2 \dim \mathfrak{b} -1].
\]

(6.16)

To calculate the value at \( \bar{\lambda}(t) \) of the integral of the basic function that was denoted by \( \pi \Phi_0 \) in the introduction, for \( \bar{\lambda} \) fixed by Frobenius, we need to calculate the (alternating) trace of Frobenius on the fiber of \( \tilde{\pi}_l(\text{IC}_{\mathcal{V}}^{\bar{\lambda}}) \) over an \( \mathbb{F} \)-point of the diagonal \( C \hookrightarrow A^{\bar{\lambda}} \), and then multiply
by the factor $tr_F(\text{Fr}, \Lambda^*(\mathfrak{n}(1)))$ in order to account for the difference between $\text{IC}_Y$ and $\text{IC}_{\overline{Y}}$ (Corollary 4.5.7).

Taking into account the twists in the intersection complexes of the $C^n$s in (6.12), we deduce that, with this normalization of the IC sheaves, Frobenius acts on at that fiber as on

$$\bigoplus_{\deg(b) = \lambda} \left( \bigotimes_{\mu} \text{Sym}^N_b \left( \bigoplus_{b \in \mathfrak{B}_{X, \mu}} \overline{\text{IC}}_b(-\dim b)[2\dim b] \right) \right).$$

Thus, in the notation of Theorems 1.1.2 and 1.1.4, we have

$$\pi_1 \Phi_0 = tr_F(\text{Fr}, \Lambda^*(\mathfrak{n}(1))) \cdot tr_F(\text{Fr}, \text{Sym}^*(\bigoplus_{b \in \mathfrak{B}_{X}} \overline{\text{IC}}_b(-\dim b))),$$

where we remind that $\mathfrak{B}_X = \bigcup_{\rho \in \mathcal{C}_X} \mathfrak{B}_{X, \rho}$.

The dimensions $\dim b$ are given by Proposition 6.5.1: they are either equal to $\frac{1}{2}(\text{len}(D) - 1)$, if $b$ meets $\mathfrak{Y}^{P,\rho}$, or $\langle \rho_G, \lambda - \hat{\theta} \rangle$, if $b$ meets $\mathfrak{Y}^{\lambda, \theta}$ for $\hat{\theta} \in D_{\text{sat}, \mathfrak{B}}(X)$.

Both theorems assume the existence of a $G$-eigen-volume form on $X^*$, which we fix, with eigencharacter $\eta$. We denote the absolute value of this eigencharacter by $\eta$. By Remark 5.4.4, for any $D \in \mathbb{N}_0$ with $g_X(D) = \lambda$, we have $\text{len}(D) = \langle \eta + 2\rho_G, \lambda \rangle$. Having defined $q^2$ to be the trace of $\text{Fr}$ on $Q(\frac{1}{2})[1]$, the effect of multiplying by $(\eta \theta)^2(t)$ will be to replace $\overline{\text{IC}}_b(-\dim b)$, in the expression above, by $\overline{\text{IC}}(\frac{1}{2})(1)$, for those $b$ in $\mathfrak{Y}^{P,\rho}$; this proves Theorem 1.1.2.(i),(iv),(v).

For the rest of the components $b$, taking into account that $\lambda \geq \theta$ and $\eta$ is trivial on the roots, therefore $\langle \eta, \lambda \rangle = \langle \eta, \theta \rangle$ and $\gamma$ has the same parity as $\gamma + 2\rho_G, \theta$, the effect of multiplying by $(\eta \theta)^2(t)$ will be to replace $\overline{\text{IC}}_b(-\dim b)$ by $\overline{\text{IC}}(\frac{h+2\rho_G, \theta}{2})(1)$, proving Theorem 1.1.4.

The remaining parts, (ii), (iii) of Theorem 1.1.2 will follow directly from Theorem 7.1.9.

7. The crystal of a spherical variety

We keep the assumptions of $\S 5$–6. In this section, we study the irreducible components of central Zastava fibers of critical dimension (Proposition 6.5.1) which give rise to the “new” contributions $V_{X, \lambda}$ to the pushforward of the IC sheaf by Proposition 6.4.1. Our main result is that these components give rise to a crystal, in the sense of Kashiwara, if we formally attach to them their “negatives”. Since these components are, by Proposition 6.5.1, of two different kinds, namely those associated to the Zastava space of the open $G$-orbit $X^*$ and those associated to certain strata of the affine Grassmannian, and the relation of the latter to crystals is well-known by [BG01, BFG06], the problem quickly reduces to the study of the crystal associated to $X^*$.

7.1. The crystal $\mathfrak{B}_X$.

7.1.1. Definition of crystal. We review the definition of crystal, in the sense of Kashiwara [Kas93], over the Langlands dual Lie algebra $\hat{\mathfrak{g}}$. We refer the reader to [Kas94, Kas95, BS17, HK02] for further details on crystals, which can be associated to any Kac–Moody algebra.

Let $I$ denote the set of vertices of the Dynkin diagram associated to $G$, so $\{\alpha_i\}_{i \in I} = \Delta_G$ is the set of simple roots of $G$.

A crystal $\mathfrak{B}$ over $\hat{\mathfrak{g}}$ is a set with the following data:

$$\text{wt}: \mathfrak{B} \to \hat{\Lambda}_G$$

$$\varepsilon_i, \varphi_i: \mathfrak{B} \to \mathbb{Z} \sqcup \{-\infty\} \quad \text{for } i \in I,$$

$$\tilde{\varepsilon}_i, \tilde{\varphi}_i: \mathfrak{B} \to \mathbb{Z} \sqcup \{0\} \quad \text{for } i \in I.$$
satisfying the following axioms:

1. \( \varphi_i(b) = \varepsilon_i(b) + \langle \alpha_i, \text{wt}(b) \rangle \) for \( b \in \mathcal{B} \), \( i \in I \).
2. If \( b \in \mathcal{B} \) and \( \varepsilon_i b \neq 0 \), then
   \[
   \text{wt}(\varepsilon_i b) = \text{wt}(b) + \alpha_i, \quad \varepsilon_i(\varepsilon_i b) = \varepsilon_i(b) - 1, \quad \varphi_i(\varepsilon_i b) = \varphi_i(b) + 1.
   \]
3. If \( b \in \mathcal{B} \) and \( \tilde{f}_i b \neq 0 \), then
   \[
   \text{wt}(\tilde{f}_i b) = \text{wt}(b) - \alpha_i, \quad \varepsilon_i(\tilde{f}_i b) = 1, \quad \varphi_i(\tilde{f}_i b) = \varphi_i(b) - 1.
   \]
4. For \( b_1, b_2 \in \mathcal{B} \), \( b_2 = \tilde{f}_i b_1 \) if and only if \( b_1 = \varepsilon_i b_2 \).
5. If \( \varphi_i(b) = -\infty \), then \( \varepsilon_i b = \tilde{f}_i b = 0 \).

A crystal \( \mathcal{B} \) is called seminormal\(^{19}\) if

\[
\varepsilon_i(b) = \max\{n \geq 0 \mid \varepsilon_i^n b \in \mathcal{B}\} \in \mathbb{N}, \quad \varphi_i(b) = \max\{n \geq 0 \mid \tilde{f}_i^n b \in \mathcal{B}\} \in \mathbb{N}
\]

for all \( b \in \mathcal{B}, i \in I \). From now on we will only consider seminormal crystals, so the maps \( \varepsilon_i, \varphi_i \) are uniquely determined by \( \text{wt}, \varepsilon_i, \tilde{f}_i \).

Kashiwara showed the existence and uniqueness of crystal bases for any integrable module of the quantized enveloping algebra \( U_q(\mathfrak{g}) \). A crystal \( \mathcal{B} \) is called normal if it is isomorphic to the crystal basis of an integrable \( U_q(\mathfrak{g}) \)-module.

For any subset \( J \subset I \), let \( \mathfrak{g}_J \) denote the corresponding Levi subalgebra. For a crystal \( \mathcal{B} \) of \( \mathfrak{g}_J \), let \( \Phi_J(\mathcal{B}) \) denote \( \mathcal{B} \) regarded as a crystal over \( \mathfrak{g}_J \). Then saying that \( \mathcal{B} \) is seminormal is equivalent to saying that \( \Phi_J(\mathcal{B}) \) is isomorphic to the crystal basis of an integrable \( U_q(\mathfrak{g}_J) \)-module. One can check the normality of a crystal by restricting to every pair of vertices in the Dynkin diagram:

**Proposition 7.1.2** ([KKM+92, Proposition 2.4.4], [BS17, Theorem 5.21]). Let \( \mathcal{B} \) be a finite crystal over \( \mathfrak{g}_J \) such that for every subset \( \{i, j\} \subset I \), the crystal \( \Phi_{\{i, j\}}(\mathcal{B}) \) is isomorphic to the crystal basis of a finite-dimensional \( U_q(\mathfrak{g}_{\{i, j\}}) \)-module. Then \( \mathcal{B} \) is normal.

For a crystal \( \mathcal{B} \) one can construct an oriented crystal graph with vertex set \( \mathcal{B} \) and edges given by the \( \tilde{f}_i \). We can decompose \( \mathcal{B} \) into a disjoint union of crystals corresponding to the connected components of the crystal graph. We will call these the connected components of \( \mathcal{B} \).

For \( \lambda \in \Lambda^+_\mathfrak{g} \), there is a unique crystal basis \( \mathcal{B}^\lambda_{\mathfrak{g}} \) for the irreducible highest weight module \( V^\lambda \) of \( U_q(\mathfrak{g}) \). (We will abuse notation and use \( V^\lambda \) to denote both the representation of the quantized enveloping algebra and its classical limit at \( q = 1 \), which is the corresponding irreducible \( \mathfrak{g} \)-module.) In other words, there is a unique normal connected crystal with highest weight vector of weight \( \lambda \). However, we warn that in general there may be many seminormal connected crystals with the same property.

Given a crystal \( \mathcal{B} \), we can define a crystal \( \mathcal{B}^\vee \) by “reversing the arrows”: the set \( \mathcal{B}^\vee = \{ b^\vee \mid b \in \mathcal{B} \} \) is formally the same as \( \mathcal{B} \), and \( \text{wt}(b^\vee) = -\text{wt}(b) \). The roles of \( \varepsilon_i, \tilde{f}_i \) are swapped. The crystal \( (\mathcal{B}^\lambda_{\mathfrak{g}})^\vee \) is isomorphic to the crystal basis of the irreducible \( U_q(\mathfrak{g}) \)-module of lowest weight \(-\lambda \), which we also denote by \( V^{\lambda^\vee} \).

7.1.3. Let us mention an important consequence of the structure of a seminormal crystal \( \mathcal{B} \). Let \( W \) be the free group generated by \( \{ s_i \mid i \in I \} \) with the relation \( s_i^2 = 1 \). The Weyl group \( W \) is the quotient of \( W \) by the braid relations.

\(^{19}\)This is the terminology of [Kas94, Kas95]. In [Kas93] the term normal was used for what we call seminormal.
It follows from the classification of integrable $U_q(\mathfrak{sl}_2)$-modules that we have a natural action of $\mathcal{W}$ on $\mathcal{B}$ defined by

$$s_i(b) = \begin{cases} f_i^\alpha(b) & \text{if } \langle \alpha, \text{wt}(b) \rangle \geq 0 \\ e_i^{-\alpha}(b) & \text{if } \langle \alpha, \text{wt}(b) \rangle \leq 0 \end{cases}$$

for $b \in \mathcal{B}_X$. For $\bar{w} \in \mathcal{W}$ we have $\text{wt}(\bar{w}b) = \bar{w}(\text{wt}(b))$, where $\mathcal{W}$ acts on $\tilde{\Lambda}_G = \tilde{\Lambda}_X$ through $W$. In other words, we have isomorphisms

$$\bar{w} : \mathcal{B}_\lambda \xrightarrow{\sim} \mathcal{B}_{\bar{w}\lambda}$$

a priori depending on $\bar{w} \in \mathcal{W}$ for all $\lambda \in \tilde{\Lambda}_G$.

If $\mathcal{B}$ is normal, the $\mathcal{W}$-action on $\mathcal{B}$ factors through $W$.

7.1.4. Definition of $\mathcal{B}_X$. For $\lambda \in \mathfrak{c}_X$, we have defined the set $\mathcal{B}_{\mathfrak{c}_X,\lambda}$ to consist of the irreducible components of $Y^\lambda$ of critical dimension (Proposition 6.5.1), that is:

- if $\lambda \in \mathfrak{c}_X^\circ$, the irreducible components of $Y^\lambda$ (or, equivalently, of $Y^\lambda_{\mathfrak{c}_X} = Y^{\lambda,0}$) of dimension $\frac{1}{2}(\text{len}(\lambda) - 1)$;
- the irreducible components of $S^\lambda \cap \text{Gr}^\theta_G$ of dimension $\langle \rho_G, \lambda - \theta \rangle$, for $\theta \in \mathcal{D}^G_{\text{sat}}(X)$, identified with their image in $Y^\lambda$ through the action map (5.14).

Note that $\lambda = 0$ never satisfies the above conditions.

Define $\mathcal{B}_{\mathfrak{c}_X,-\lambda} := \mathcal{B}_{\mathfrak{c}_X,\lambda}$, which is well-defined since $\mathcal{C}_0(X)$ is strictly convex. Let

$$\mathcal{B}_X^+ = \bigcup_{\lambda \in \mathfrak{c}_X} \mathcal{B}_{\mathfrak{c}_X,\lambda}, \quad \mathcal{B}_X^- = \bigcup_{\lambda \in \mathfrak{c}_X} \mathcal{B}_{\mathfrak{c}_X,-\lambda}.$$

In other words $\mathcal{B}_X^+$ is the set of all irreducible components of the central fiber of $\mathfrak{y}$ of the maximum dimensions satisfying the semi-smallness equality.

We (rather artificially) define $\mathcal{B}_X = \mathcal{B}_X^+ \cup \mathcal{B}_X^-$. Let $\text{wt} : \mathcal{B}_X \to \mathfrak{c}_X$ be the map sending $\mathcal{B}_{\mathfrak{c}_X,\lambda}$ to $\lambda$.

Theorem 7.1.5. The set $\mathcal{B}_X$ has the structure of a semi-normal crystal over $\mathfrak{g}$ such that the defining bijection $\mathcal{B}_X^+ \leftrightarrow \mathcal{B}_X^-$ is an isomorphism of crystals $\mathcal{B}_X \cong \mathcal{B}_X^\vee$.

The statement of the theorem above is not optimal, of course, as it does not specify all the data that give rise to the structure of a crystal, such as the operations $\tilde{e}_i, \tilde{f}_i$. To do so, we will need to introduce a process of “reduction to a Levi”, in particular, a Levi of semisimple rank one, that will provide these operators. We will define these operators, giving the structure of a self-dual semi-normal crystal to $\mathcal{B}_X$, in §7.2.5.

Conjecture 7.1.6. The crystal $\mathcal{B}_X$ is isomorphic to the unique crystal basis of a finite-dimensional $U_q(\mathfrak{g})$-module $V_X$.

In Remark 7.2.6 we explain that it suffices to prove Conjecture 7.1.6 when $G$ has semisimple rank 2, where there are finitely many cases (corresponding to the wonderful varieties in [Was96] with only spherical roots of type $T$).

7.1.7. Reduction to $X^\bullet$. Theorem 7.1.5 and Conjecture 7.1.6 immediately reduce to the study of the irreducible components of critical dimension in the central fiber of $\mathfrak{y}_X^\bullet$:

Lemma 7.1.8. Let $\mathcal{B}_X^\circ = \mathcal{B}_X \times_{\tilde{\Lambda}_X} \tilde{\Lambda}_X^\circ$, hence $\mathcal{B}_X^\circ$ is the set of irreducible components of central fibers of $\mathfrak{y}_X^\bullet$ of critical dimension. Define $\mathcal{B}_X^\bullet$ and $\mathcal{B}_X^\circ$ as before.
Then, Theorem 7.1.5 and Conjecture 7.1.6 hold if they hold for \( \mathfrak{B}_X^\bullet \), with a decomposition of the crystal \( \mathfrak{B}_X \) into a disjoint union of crystals:

\[
\mathfrak{B}_X = \mathfrak{B}_X^\bullet \sqcup \bigsqcup_{\hat{\theta} \in \pm \mathcal{D}_{\text{sat}}(X)} \mathfrak{B}_\hat{\theta}^\bullet,
\]

where \( \mathfrak{B}_\hat{\theta}^\bullet \) is the crystal associated to the irreducible \( U_q(\hat{\mathfrak{g}}) \)-module \( V_{\hat{\theta}} \) of lowest weight \( \hat{\theta} \), if \( \hat{\theta} \in \mathcal{D}_{\text{sat}}(X) \subset \hat{\lambda}_G \), or highest weight \( \hat{\theta} \) if \( -\hat{\theta} \in \mathcal{D}_{\text{sat}}(X) \).

**Proof.** Indeed, by Proposition 6.5.1, the elements of \( \mathfrak{B}_X^\bullet \) consist of elements of \( \mathfrak{B}_X^\bullet \) and irreducible components of \( S^\lambda \cap G_{\hat{\mathfrak{g}}}^\theta \), of dimension \( \langle \rho_G, \lambda - \theta \rangle \), for \( \hat{\theta} \in \mathcal{D}_{\text{sat}}(X) \). As explained in [BG01], the latter can be identified with the canonical basis for the \( \lambda \)-eigenspace of the irreducible \( U_q(\hat{\mathfrak{g}}) \)-module \( V_{\hat{\theta}} \) of lowest weight \( \hat{\theta} \). \( \square \)

While the methods of this paper are insufficient to prove Conjecture 7.1.6 for \( \mathfrak{B}_X^\bullet \), we do show that it must satisfy the following properties in §7.3.

**Theorem 7.1.9.** The crystal \( \mathfrak{B}_X^\bullet \) has the following properties:

(i) The set \( \text{wt}(\mathfrak{B}_X^\bullet) \) is equal\(^{20}\) to the set of weights of \( \bigoplus_{\lambda \in \hat{\Lambda}_G^+ \cap W_{\text{G}(D)} \mathfrak{g}} V_{\lambda} \), where \( \hat{\Lambda}_G^+ \cap W_{\text{G}(D)} \mathfrak{g} \) denotes the dominant Weyl translates of valuations of colors.

(ii) If \( b \in \mathfrak{B}_X^\bullet \), then there is a sequence of lowering operators \( \hat{f}_j \), sending \( b \) to an element of \( \mathfrak{B}_{X^\bullet,\rho_D} \) for some color \( D \in \mathcal{D} \).

(iii) For \( \lambda \in W_{\text{G}(D)} \mathfrak{g} \), the cardinality of \( \mathfrak{B}_{X^\bullet,\lambda} \) is equal to 1, unless \( \hat{\lambda} = \frac{\hat{\gamma}}{2} \) for some (not necessarily simple) coroot \( \hat{\gamma} \), in which case the cardinality is 2.

**Remark 7.1.10.** The “multiplicity 2” case appears when two colors have the same valuation, e.g., \( X = \mathbb{G}_m \setminus \text{PGL}_2 \); see §2.1.

**Remark 7.1.11.** Note that if Conjecture 7.1.6 is true, then properties (i)–(iii) of Theorem 7.1.9 uniquely determine the \( U_q(\hat{\mathfrak{g}}) \)-module \( V_X^\bullet \): it must be isomorphic to

\[
\bigoplus_{\lambda \in \hat{\Lambda}_G^+ \cap W_{\text{G}(D)} \mathfrak{g}} V_{\lambda}^{\otimes |\mathfrak{B}_{X^\bullet,\lambda}|} \oplus \bigoplus_{\hat{\theta} \in \pm \mathcal{D}_{\text{sat}}(X)} V_{\hat{\theta}},
\]

where the cardinality of \( \mathfrak{B}_{X^\bullet,\lambda} \) is specified by property (iii).

**Corollary 7.1.12.** If all coweights in \( \hat{\Lambda}_G^+ \cap W_{\text{G}(D)} \mathfrak{g} \) are miniscule, then Conjecture 7.1.6 holds, i.e., \( \mathfrak{B}_X \) is the crystal basis of the \( U_q(\hat{\mathfrak{g}}) \)-module given by (7.3).

**Proof.** This is immediate from Theorems 7.1.5, 7.1.9 and §7.1.3 after we make the assumption \( c_X^\bullet = \mathbb{N}^\mathcal{D} \), which is allowed by (5.6). \( \square \)

We also show in Corollary 7.3.3 that if \( X \) is affine homogeneous (equivalently, \( H \) is reductive), then all coweights in \( \hat{\Lambda}_G^+ \cap W_{\text{G}(D)} \mathfrak{g} \) must be miniscule.

### 7.2. Reduction to Levi.

From now on, having reduced the problem to giving a crystal structure to the set \( \mathfrak{B}_X^\bullet \), we may (by (5.6)) and will assume, unless otherwise specified, that \( X = X^\text{can} \) and \( c_X \cong \mathbb{N}^\mathcal{D} \). Under this assumption, \( \mathfrak{g}^{\hat{\lambda},0} \) is dense in \( \mathfrak{g}^\hat{\lambda} \) by Corollary 5.7.2, and \( \mathfrak{B}_X = \mathfrak{B}_X^\bullet \). Moreover, any \( \hat{\lambda} \geq 0 \) is an element of \( \mathbb{N}^\mathcal{D} \), so the length function \( \text{len} \) is a function of \( \hat{\lambda} \).

\(^{20}\text{Here we only describe an equality of sets counted without multiplicities.}\)
Let $P$ be a standard parabolic subgroup of $G$, i.e., $P \supset B$. Let $N_P$ denote its unipotent radical and $M = P/N_P$ the Levi quotient. Observe that the map $X \to X\!\!/N$ factors through $X \to X\!\!/N_P \to X\!\!/N$. Set 

$$X_M := X\!\!/N_P = \text{Spec} k[X]^{\!\!/N_P}.$$ 

Then $X_M$ is an affine spherical $M$-variety and the map $X \to X_M$ is $M$-equivariant. However, note that even if $X = X^{\text{can}}$, it will not in general be true that $X_M$ is the canonical embedding of $X_M^\bullet$. We will use this to our advantage later, using the crystals of Lemma 7.1.8 to produce the $\tilde{e}_i, \tilde{f}_i$ operations, when $M$ is taken to have semisimple rank one.

For now, we work with a general parabolic $P$. Let $B_M$ denote the image of a Borel subgroup $B$ in $M$. We have $k[X]^{(B)} = k[X_M]^{(B_M)}$, therefore $c_{X_M} = c_X$. On the other hand, $c_{X_M} \cap \tilde{X}$ is, in general, larger than $c_X$. The open $P$-orbit $X^{\circ}P$ maps to the open $M$-orbit $X_M^\bullet$, and we have

**Lemma 7.2.1.** The preimage of $X_M^\bullet$ under the quotient map $X \to X_M$ coincides with the open $P$-orbit $X^{\circ}P$, and the quotient stacks $X^{\circ}P/P$ and $X_M^\bullet/M$ are isomorphic.

**Proof.** A color $D \in \mathcal{D}$ belongs to the open $P$-orbit $X^{\circ}P$ if and only if $D \in \mathcal{D}(\alpha)$ for some $\alpha \in \Delta_M$; otherwise, it is $P$-stable, and induces an $M$-stable valuation on $k[X_M]$, which is the function field of $k[X]^{\!\!/N_P}$. This valuation is nontrivial (because it is nontrivial on $k[X]^{(B)} = k[X_M]^{(B_M)}$), therefore the image of $D$ cannot belong to $X_M^\bullet$.

Since, by our assumptions on $X$, $N$ acts freely on $X^{\circ}$, the subgroup $N_P$ acts freely on $X^{\circ}P$, and therefore $X^{\circ}P/P = (X^{\circ}P/N_P)/M = X_M^\bullet/M$. \qed

Define the parabolic Zastava model 

$$\mathcal{Y}_{X,P} := \text{Maps}_{\text{gen}}(C, X/P \supset X^{\circ}P/P) \subset \mathcal{M}_X \times_{\text{Bun}_G} \text{Bun}_P,$$ 

which naturally maps to $\text{Bun}_P$. The Cartesian diagram

$$\begin{array}{ccc}
X/B & \longrightarrow & X/P \\
\downarrow & & \downarrow \\
X_M/B_M & \longrightarrow & X_M/M
\end{array}$$

gives rise to a diagram

$$\begin{array}{ccc}
\mathcal{Y}_\lambda_X & \longrightarrow & \mathcal{Y}_X & \longrightarrow & \mathcal{Y}_{X,P} \\
\downarrow & & \downarrow & & \downarrow \pi_{X,P} \\
\mathcal{Y}_\lambda_{X,M} & \longrightarrow & \mathcal{Y}_{X_M} & \longrightarrow & \mathcal{M}_{X_M}
\end{array}$$

(7.4)

with all squares Cartesian. Central fibers are taken with respect to a fixed point $v \in [C]$.

Our goal is to study the components of critical dimension of $\mathcal{Y}_\lambda_X$ in terms of $\mathcal{Y}_\lambda_{X,M}$ and the fibers of the map $\pi_{X,P}$. At this point, it will be critical to distinguish the stratum $\mathcal{Y}_{X,M}^{\lambda,\delta}$ where the image of the generic point of a component $b \in \mathcal{B}_{X,M}$ lies, that is, the $M(\alpha_v)$-orbit of its image in $X_M(\alpha_v)$ (after trivialization in a formal neighborhood of $v$). The reason is, as we are about to see, that this stratum will completely determine the fiber of the map $\pi_{X,P}$ over the image.

Indeed, recall from §4.3 that lifting a point from $\mathcal{M}_{X_M}$ to $\mathcal{Y}_\lambda_{X,M}$ induces a trivialization of the corresponding $G$-bundle away from $v$ (depending on a fixed choice of base point $x_0 \in X^{\circ}$),
Hence we have a commutative diagram as defined in (5.13). Similarly, the map of the affine Grassmannian $\text{Gr}$ follows: Consider the decomposition of $B$ by Lemma 7.2.1, so the fibers are singletons. □

Remark 7.2.3. At this point, we would like to emphasize a fine point in the arguments that follow: Consider the decomposition of $\mathfrak{B}^+_{X,M}$ according to (7.2) (restricted to the + - part):

$$
\mathfrak{B}^+_{X,M} = \mathfrak{B}^+_{X_M} \sqcup \bigcup_{\tilde{\delta} \in D^+_m(X_M)} \mathfrak{B}^\delta_{m}
$$

with all squares Cartesians.

Let $H_M$ be the stabilizer in $P$ of the base point $x_0$. By Lemma 7.2.1, it is isomorphic to the stabilizer in $M$ of the image of $x_0$ in $X_M$. We first note:

**Lemma 7.2.2.** For any $\tilde{\delta} \in c_{X_M}^-$, the fibers of the map of ind-schemes

$$(7.6) \quad \text{Gr}_M \times_{LX_M/L^+M} (L^+X_M/L^+M) \to \text{Gr}_M \times_{LX_M/L^+M} (L^+X_M/L^+M)$$

over the stratum $L^\delta X_M/L^+M$ are isomorphic under the $LH_M$-action, and this action gives rise to a canonical bijection between the irreducible components of any two fibers.

More precisely, all fibers are isomorphic to $\{t\} \times \mathcal{X}_M$, $\mathcal{Y}_{X,P}$ and of dimension $\leq \frac{1}{2}(\text{len}(\tilde{\delta}) - 1)$, unless $\tilde{\delta} = 0$, in which case the restriction of (7.6) to the $\tilde{\delta}$-stratum is an isomorphism.

Notice that, under our assumption that $c_X \cong \mathbb{N}^D$ since the beginning of this subsection, $\text{len}(\tilde{\delta})$ makes sense.

**Proof.** Since $LH_M$ acts transitively on $\text{Gr}_M \times_{LX_M/L^+M} (L^\delta X_M/L^+M)$, the first statement is obvious.

We may now choose the point $t^\delta \in Y_{X_M}^\delta$, whose image in $L^+X_M/L^+M$ lies in the $\tilde{\delta}$-stratum — in fact, by Corollary 5.5.6, $Y_{X_M}^\delta = \{t^\delta\}$. By Corollary 2.3.2, the stabilizer in $LH_M$ of its image $t^\delta \in \text{Gr}_M$ is connected. Therefore, the action of $LH_M$ induces a canonical bijection between irreducible components of the fibers.

Finally, if $\tilde{\delta} \neq 0$, the dimension of $Y_{X_M}^\delta$ is $\leq \frac{1}{2}(\text{len}(\tilde{\delta}) - 1)$, as explained in Proposition 6.5.1, and therefore so is, a fortiori, the dimension of the fiber over $Y_{X_M}^{\delta,\tilde{\delta}} = \{t^\delta\}$. For $\tilde{\delta} = 0$, we observe that

$$
\mathcal{Y}_{X,P} \times_{\mathcal{X}_M} \mathcal{M}_{X,M} = \text{Maps}(C, X^o P/P) = \text{Maps}(C, X_M^\bullet /M) = \mathcal{X}_M^{\delta,\tilde{\delta}}
$$

by Lemma 7.2.1, so the fibers are singletons. □
(where we have denoted $\mathfrak{B}_{\tilde{\theta}}$ by $\mathfrak{B}_{\tilde{\theta}}^\theta$, to emphasize that it corresponds to the $\tilde{\theta}$-lowest weight crystal of a $\tilde{m}$-module). We will not claim that the map $q$ of (7.4) induces a map from $\mathfrak{B}_{X_M}^\theta$ to $\mathfrak{B}_{X_M}^\theta$. Indeed, the generic fiber of a $b \in \mathfrak{B}_{X_M}$ may map to the image of $S^\lambda_M \cap Gr^\theta_M \to Y^\lambda_{X_M}$ (where $S^\lambda_M$ denotes the semi-infinite orbit corresponding to $\lambda$ in $Gr_M$), for some $\tilde{\theta} \in \mathfrak{c}_{X_M}$ that is not an element of $D^\lambda_M(X_M)$. These are the MV cycles that were discussed in Remark 6.5.2, which are not "of critical dimension" in terms of $X_M$. Representation-theoretically, if we believe that $\mathfrak{B}_X$ corresponds to a representation of $\tilde{G}$ (as predicted by Conjecture 7.1.6), this just says that the $\tilde{M}$-lowest weights of the spans of some vectors do not need to be extremal in $\mathfrak{c}_{X_M}^{\tilde{M}}$; however, in §7.3 we will see that there are weight-lowering operators $\tilde{f}_i$, possibly corresponding to roots not in $\tilde{M}$, which eventually lower such weights to the weight of a color.

For that reason, for the following proposition, which is the main technical result of this subsection, we denote by $\mathfrak{B}_{\mathfrak{m}}^\theta$ the crystal corresponding to the representation of $\mathfrak{m}$ of lowest weight $\tilde{\theta}$, that is, the set of irreducible components of $S^\lambda_M \cap Gr^\theta_M$ of the maximal dimension $\langle \rho_M, \lambda - \tilde{\theta} \rangle$, for any $\tilde{\theta} \in \mathfrak{c}_{X_M}$.

**Proposition 7.2.4.** For any $\lambda \in \mathfrak{c}_{\mathfrak{X}}$, the diagram (7.4) induces a canonical decomposition

$$
\mathfrak{B}_{X,\lambda} = \bigsqcup_{\tilde{\theta} \in \mathfrak{c}_{X_M}^{\tilde{M}}} \mathfrak{B}_{X,\theta}^{\mathfrak{P}} \times \mathfrak{B}_{\mathfrak{m},\lambda}^{\theta},
$$

where $\mathfrak{B}_{X,\theta}^{\mathfrak{P}}$ denotes the set of irreducible components of $\{t^\theta\}_M \times_{\mathfrak{X}_M} \mathfrak{Y}_{X,\mathfrak{P}}$ of dimension $\frac{1}{2}(\text{len}(\tilde{\theta}) - 1)$.

Taking the union over all such $\lambda$, we get

$$
\mathfrak{B}_{X,\mathfrak{X}} = \bigsqcup_{\tilde{\theta} \in \mathfrak{c}_{X_M}^{\tilde{M}}} \mathfrak{B}_{X,\theta}^{\mathfrak{P}} \times \mathfrak{B}_{\mathfrak{m}}^{\theta}.
$$

The set $\mathfrak{B}_{X,\theta}^{\mathfrak{P}}$ should be thought of as the multiplicity space for the irreducible representation with basis $\mathfrak{B}_{\mathfrak{m}}^{\theta}$, and is something of a "black box" to us.

**Proof.** The dimension yoga here goes as follows: Let $b \in \mathfrak{B}_{X,\lambda}$, and suppose that its generic point lands in the stratum $Y^\lambda_{X,\theta}$ under the map $q$ of (7.5).

If $\tilde{\theta} = 0$, then $\lambda \geq \mathfrak{X}_M^\mathfrak{0}$, i.e., it belongs to the positive span of colors in $X_M$, hence $\text{len}(\lambda)$ is the same, whether we define it with respect to $X$ or with respect to $X_M$. By Lemma 7.2.2 the irreducible components of critical dimension $\frac{1}{2}(\text{len}(\lambda) - 1)$ of $\mathfrak{Y}_X$ and $\mathfrak{Y}_{X,\mathfrak{X}}$ are in bijection, hence the set of $b \in \mathfrak{B}_{X,\lambda}$ which map generically to $Y^\lambda_{X,\theta}$ is identified with $\mathfrak{B}_{X,\lambda}$.

If $\tilde{\theta} \neq 0$, then $q$ sends $b$ to $Y^\lambda_{X,\theta}$, which has dimension $\leq \frac{1}{2}\text{len}(\lambda - \tilde{\theta})$ by Lemma 6.5.3. On the other hand, Lemma 7.2.2 states that the dimension of the corresponding fibers of $\pi_{X,\theta}$ is $\leq \frac{1}{2}(\text{len}(\tilde{\theta}) - 1)$. Thus, the only way that $b$ is of critical dimension $\frac{1}{2}(\text{len}(\lambda) - 1)$ is if both inequalities are equalities. In this case Lemma 6.5.3 implies that $\lambda \geq \tilde{\theta}$ and the generic point of $b$ is sent under the map $(\text{act}_v \circ \mathfrak{X}_M \circ q)$ to an element of $\mathfrak{B}_{X,\theta}^{\mathfrak{P}} \times \mathfrak{B}_{\mathfrak{m},\lambda}^{\theta}$. Vice versa, for any irreducible component (MV cycle) of dimension $\langle \rho_M, \lambda - \tilde{\theta} \rangle$ of $S^\lambda_M \cap Gr^\theta_M$ (i.e., every element of $\mathfrak{B}_{\mathfrak{m},\lambda}$), Lemma 5.5.11 guarantees that it corresponds to a component $b'$ of $Y^\lambda_{X,\theta}$ of the same dimension, and Lemma 7.2.2 ensures that the components of $Y^\lambda_{X,\theta}$ of critical dimension in the preimage of $b'$ are in canonical bijection with $\mathfrak{B}_{X,\theta}^{\mathfrak{P}}$. \qed
7.2.5. Kashiwara operations $\bar{e}_i, \bar{f}_i$. For $i \in I$ let $P_i = P_{\alpha_i}$ denote the corresponding parabolic subgroup of semisimple rank one. Let $M_i$ denote the Levi factor. Then the Langlands dual Lie algebra $\mathfrak{g}_{(i)}$ in our previous notation. Applying Proposition 7.2.4 to $M_i$ we get the disjoint union

$$\mathcal{B}_X^+ = \mathcal{B}_{X, M_i}^+ \sqcup \bigsqcup_{\theta \in c_i^- - 0} \mathcal{B}_{X, \theta}^P \times \mathcal{B}_{M_i}^\theta,$$

where $c_i^- = c_{X, M_i}$.

Now, by our “type $T$” assumption (see §2.1.1), $X_{M_i}^*/B_{M_i} = \mathbb{G}_m \setminus \mathbb{P}^1$ as stacks. Therefore $\mathcal{Y}_{X_{M_i}} = \text{Sym} C \times \text{Sym} C$ (see Example 3.3.1) and $\mathcal{Y}_{X_{M_i}}^+$ consists of two elements, which can be identified with their images $\bar{\nu}_i^\pm$ in $\Lambda$, $\bar{\nu}_i^\pm = \mathcal{Q}_X(D_{\alpha_i}^\pm)$ are the valuations of the two colors in $D(\alpha_i)$. Therefore, we have a bijection of sets

$$\mathcal{B}_X^+ = \mathcal{B}_X^+ \cup \mathcal{B}_X^- = \{\bar{\nu}_i^+, \bar{\nu}_i^-, -\bar{\nu}_i^+, -\bar{\nu}_i^-\} \sqcup \bigsqcup_{\theta \in c_i^- - 0} \mathcal{B}_{X, \theta}^P \times (\mathcal{B}_{M_i}^\theta \sqcup (\mathcal{B}_{M_i}^\theta)^\vee).$$

Observe that $\{\bar{\nu}_i^+, -\bar{\nu}_i^-\}$ is in bijection with the normal crystal $\mathcal{B}_{\bar{M}_i}^\circ$ since $\langle \alpha_i, \nu_i^+ \rangle = 1$ and $\bar{\nu}_i^+ - \bar{\alpha}_i = -\bar{\nu}_i^-$. We also observe that $\{\bar{\nu}_i^+, -\bar{\nu}_i^+\} = \mathcal{B}_{\bar{M}_i}^\circ = (\mathcal{B}_{\bar{M}_i}^\circ)^\vee$ as sets.

Now we simply define the operations $\bar{e}_i, \bar{f}_i$ such that

(7.9) \[ \Phi_{(i)}(\mathcal{B}_X^+) = \mathcal{B}_{\bar{M}_i}^\circ \cup \mathcal{B}_{\bar{M}_i}^\circ \sqcup \bigsqcup_{\theta \in c_i^- - 0} \mathcal{B}_{X, \theta}^P \times (\mathcal{B}_{M_i}^\theta \sqcup (\mathcal{B}_{M_i}^\theta)^\vee) \]

as normal crystals over $\bar{M}_i$, where $\mathcal{B}_{X, \theta}^P$ is treated as an abstract set. This gives the structure of a seminormal crystal over $\mathfrak{g}$ to $\mathcal{B}_X$, such that the bijection $\mathcal{B}_X^+ \leftrightarrow \mathcal{B}_X^-$ identifies it with its dual. This completes the proof of Theorem 7.1.5.

Remark 7.2.6. The decomposition (7.7) gives a decomposition into crystals over $\bar{M}_i$. Therefore if we consider Proposition 7.2.4 for all standard parabolics corresponding to $\{i, j\} \subset I$, then Proposition 7.1.2 implies that $\mathcal{B}_X$ is normal (i.e., Conjecture 7.1.6 holds) if $\mathcal{B}_{X_{M_i}}^+$ is normal for all $M$ of semisimple rank 2.

The discussion of §7.2.5 also leads to the following observation:

Lemma 7.2.7. The $W$-orbit of $\mathcal{Q}_X(D)$ is contained in $c_X^P \sqcup -c_X^P$. If $\bar{\lambda} \in \text{wt}(\mathcal{B}_X^+)$ is not in $W \mathcal{Q}_X(D)$, the entire $W$-orbit $W\bar{\lambda}$ is contained in the monoid $c_X^P$.

Proof. Let $b \in \mathcal{B}_X^+$ with $\bar{\lambda} = \text{wt}(b)$. The decomposition of $\Phi_{(i)}(\mathcal{B}_X^+)$ from §7.2.5 shows that if $\bar{\lambda} \notin \{\nu_i^\pm\}$, we have $s_i b \in \mathcal{B}_X^+$, so $s_i \bar{\lambda} \in c_X^P$. Since $s_i \bar{\nu}_i^\pm = -\bar{\nu}_i^\mp$, we can iteratively apply simple reflections to deduce the claims.

7.3. Lowering operators via hyperplane intersections. In this subsection we prove Theorem 7.1.9. Property (iii) follows from Lemma 5.4.2 and the $\tilde{W}$-action on $\mathcal{B}_X$ given by seminormality of the crystal (§7.1.3).

To prove properties (i)–(ii) we will need a geometric interpretation of the weight-lowering operators $\bar{f}_i$. This interpretation is already hiding behind the crystal structure of $\mathcal{B}_{\bar{M}_i}^\circ$ (in the notation of Proposition 7.2.4), and has to do with closure relations of semi-infinite orbits in the affine Grassmannian. To bring such closure relations into our discussion, we need to extend the considerations of §7.2 to the compactified Zastava models.
Proposition 7.3.1. For \( \hat{\lambda} \in \mathfrak{c}_X^D \), let \( b \in \mathfrak{B}_X \hat{\lambda} \) be an irreducible component of critical dimension, and let \( \overline{b} \) be its closure in \( Y^\lambda \). For \( i \in I \), consider the intersection
\[
\overline{b} \cap Y^{\lambda - \hat{\alpha}_i} \subset Y^\lambda.
\]

(i) If the above intersection is non-empty, then \( \hat{f}_i b \neq 0 \) and it corresponds to an irreducible component of dimension \( \text{dim}(b) - 1 \) of \( \overline{b} \cap Y^{\lambda - \hat{\alpha}_i} \). Vice versa, if \( \hat{f}_i b \neq 0 \) then the above intersection is non-empty, unless \( \hat{\lambda} = \hat{\nu}_i^\pm \) is a color, in which case \( b \subset Y^\lambda \) is a point.

(ii) The intersection \( \overline{b} \cap Y^{\lambda - \hat{\alpha}_i} \) is empty only if either \( \hat{\lambda} = \hat{\nu}_i^\pm \) or \( \langle \alpha_i, \hat{\lambda} \rangle \leq 0 \).

We remark that it may be possible for \( \overline{b} \cap Y^{\lambda - \hat{\alpha}_i} \) to be reducible (cf. [BFG06, Proposition 19.2]), which replaces the erroneous Proposition 15.2 of loc. cit.).

The proof of this proposition will be given at the end of this section. We first use the proposition to prove Theorem 7.1.9. Both properties (i)--(ii) rely on the following observation:

Lemma 7.3.2. For \( \hat{\lambda} \in \mathfrak{c}_X^D \) and \( b \in \mathfrak{B}_X \hat{\lambda} \) there is a sequence \( \alpha_1, \ldots, \alpha_d \) of simple roots (possibly with repetitions), where \( d = \text{dim}(b) \), such that for all \( j \) with \( 0 \leq j \leq d \), the intersection \( \overline{b} \cap S^{\lambda - \hat{\alpha}_1 - \cdots - \hat{\alpha}_j} \) is nonempty of dimension \( d - j \), and \( \hat{\lambda} - \sum_{j=1}^d \hat{\alpha}_j = \hat{\nu}_D \) for some color \( D \in \mathcal{D} \). In particular, \( \hat{\lambda} \geq \hat{\nu}_D \).

Proof. By definition, \( b \) is of critical dimension \( d = \frac{1}{2}(\text{len}(\hat{\lambda}) - 1) \). Proposition 4.4.2 shows that there exists a \( \hat{\lambda}' \leq \hat{\lambda} \) such that \( \langle \rho_G, \hat{\lambda} - \hat{\lambda}' \rangle \geq \frac{1}{2}(\text{len}(\hat{\lambda}) - 1) \), and \( b \cap S^{\hat{\lambda}} \) is nonempty of dimension zero. Proposition 6.1.1 states that the dimension inequality should be an equality, in which case Proposition 4.4.2 again provides the sequence of simple roots as in the statement. In that case, \( \text{len}(\hat{\lambda}') = 1 \), hence \( \hat{\lambda}' = \hat{\nu}_D \) for some color \( D \in \mathcal{D} \). \( \square \)

Proof of Theorem 7.1.9(ii). For any \( b \in \mathfrak{B}_X^+ \), let \( \alpha_1, \ldots, \alpha_d \) be the sequence of simple roots given by Lemma 7.3.2. Then Proposition 7.3.1(i) applied inductively shows that \( \hat{f}_{\alpha_d} \cdots \hat{f}_{\alpha_1}(b) \in \mathfrak{B}_X^+ \hat{\nu}_D \) for some \( D \in \mathcal{D} \). \( \square \)

Proof of Theorem 7.1.9(i). We assume as in §7.2 that \( \mathfrak{c}_X = \mathbb{N}^D \). First we show that the weights of \( \mathfrak{B}_X \), are contained in the weights of \( V^\lambda \) for \( \lambda \in \hat{\Lambda}_G^D \cap W_G(D) \). Let \( \hat{\theta} \in \text{wt}(\mathfrak{B}_X^+) \). By (7.1), we may assume that \( \hat{\theta} \in \hat{\Lambda}_G^D \). If \( \hat{\theta} \notin W_G(D) \), then Lemma 7.2.7 implies that \( \hat{\theta} \in \mathfrak{c}_X^D \). Now Lemma 7.3.2 gives some color \( D \in \mathcal{D} \) such that \( \hat{\nu}_D \leq \hat{\theta} \). Since \( \hat{\theta} \) is antidual, it must be a weight of \( V^\lambda \) where \( \hat{\lambda} \) is the unique dominant coweight in the \( W \)-orbit of \( \hat{\nu}_D \). If \( \alpha \) is a simple root such that \( D(\alpha) = \{ D, D' \} \), then \( s_\alpha(\hat{\nu}_D) = -\hat{\nu}_D \). Then we see that \( W_G(D) = -W_G(D) \).

Hence all of \( \text{wt}(\mathfrak{B}_X^+) \) is also contained in the weights of the claimed representations.

Next suppose that \( \hat{\mu} \) is a weight of \( V^\lambda \) for \( \hat{\lambda} \in \hat{\Lambda}_G^D \cap W_G(D) \subset \mathfrak{c}_X^D \). We will show that \( \mathfrak{B}_X^+, \hat{\mu} \) is nonempty. By Theorem 7.9(iii), there exists an element \( b \in \mathfrak{B}_X^+, \hat{\lambda} \), and by (7.1) we may assume that \( \hat{\mu} \in \hat{\Lambda}_G^D \) is also dominant. Let \( \hat{\lambda} - \hat{\mu} = \hat{\alpha}_1 + \cdots + \hat{\alpha}_d \) for a sequence of simple roots \( \hat{\alpha}_j \) (possibly with repetitions) such that \( d = \langle \rho_G, \hat{\lambda} - \hat{\mu} \rangle \). By rearranging the order, we can ensure that \( \hat{\lambda}_j = \hat{\lambda} - \hat{\alpha}_1 - \cdots - \hat{\alpha}_j \) has the property that \( \langle \alpha, \hat{\lambda}_j \rangle \geq -1 \) for all \( 0 \leq j \leq d \) and every simple root \( \alpha \). Indeed, if \( \langle \alpha, \hat{\lambda}_j + \hat{\rho}_G \rangle \leq 1 \), then \( \hat{\alpha}_{j+1} \neq \hat{\alpha}_j \). This is always possible because otherwise \( \hat{\lambda}_j - \hat{\mu} \) is a nontrivial sum of those \( \hat{\alpha}_j \)'s (with multiplicity) such that \( \langle \alpha, \hat{\lambda}_j + \hat{\rho}_G \rangle \leq 1 \), but then there exists, among those \( \hat{\alpha}_j \)'s, at least one such that \( \langle \alpha, \hat{\lambda}_j - \hat{\mu} \rangle \geq 1 \), which would imply that \( \langle \alpha, \hat{\mu} \rangle < 0 \), contradicting the assumption that \( \hat{\mu} \) is dominant. In particular, that means that \( \langle \alpha_{j+1}, \hat{\lambda}_j \rangle > 0 \), for all \( j < d \). Now, Proposition 7.3.1(ii) implies that \( \hat{f}_{\alpha_d} \cdots \hat{f}_{\alpha_1}(b) \in \mathfrak{B}_X^+, \hat{\mu} \) is nonempty. \( \square \)
Corollary 7.3.3. If $X^\bullet = H\backslash G$ is affine, then all dominant Weyl translates in $\mathring{\Lambda}_G^+ \cap W_G(D)$ are miniscule and $\mathcal{B}_X$ is a normal crystal.

Proof. Assume $X^\bullet$ is affine, so $c_{X^\bullet} = 0$. If there exists a non-miniscule coweight in $\mathring{\Lambda}_G^+ \cap W_G(D)$, then Theorem 7.1.9(i) implies that $\mathcal{B}_{X^\bullet, \hat{\theta}}$ is non-empty for some $\hat{\theta} \in c_{X^\bullet} - 0$ not in $W_G(D)$. Lemma 7.2.7 and (7.1) allow us to assume $\hat{\theta} \in c_{X^\bullet}^\circ = 0$, which gives a contradiction. \hfill \Box

7.3.4. The rest of this section is devoted to the proof of Proposition 7.3.1. We use the notation from §7.2.5. For brevity we write $X_i = X_{M_i}$, $H_i = H_{M_i}$, $B_i = B_{M_i}$ and $N_i = N_{B_i}$. We say $\bar{\mu} \leq_i \bar{\lambda}$ if $\lambda - \mu \in \mathbb{N} \bar{\alpha}_i$.

We would like to embed the left Cartesian square of (7.5) into a Cartesian square involving compactified Zastava spaces. For that purpose, consider the extension of the map $\iota_{X,M} = \iota_{X_i}$ of that diagram to $\overline{\mathcal{Y}_i^\lambda}$, and define $\mathcal{Y}_X^{\leq, \bar{\lambda}}$ by the Cartesian diagram

\[
\begin{array}{ccc}
\mathcal{Y}_X^{\leq, \bar{\lambda}} & \xrightarrow{\iota_{X,P}} & \text{Gr}_{P_i} \times_{L^+_X/P_i} (L^+_X/L^+_P) \\
\downarrow{q} & & \downarrow{\pi_{X,P}} \\
\mathcal{Y}_{X_i}^{\leq, \bar{\lambda}} & \xrightarrow{\iota_{X_i}} & \text{Gr}_{M_i} \times_{L^+_X/P_i} (L^+_X/L^+_M).
\end{array}
\]

(7.10)

Lemma 7.3.5. The scheme $(\mathcal{Y}_X^{\leq, \bar{\lambda}})_{\text{red}}$ is naturally a locally closed subscheme of $\mathcal{Y}_X^\lambda$, equal to the union of strata

$\mathcal{Y}_X^{\leq, \bar{\lambda}} = \bigcup_{n \geq 0} \mathcal{Y}_X^{\lambda - n \bar{\alpha}_i}.$

Proof. From the Cartesian diagram (7.4), we see that the stratification $\mathcal{Y}_X^\lambda = \bigcup_{n \geq 0} \mathcal{Y}_X^{\lambda - n \bar{\alpha}_i}$ induces a stratification of $\mathcal{Y}_X^{\leq, \bar{\lambda}}$ by $\bigcup_{n \geq 0} \mathcal{Y}_X^{\lambda - n \bar{\alpha}_i}$.

A point of $\mathcal{Y}_X^{\leq, \bar{\lambda}}$ is a map of stacks

$y : C \to X \times P_i / M_i / N_i \times T$

such that $C - v$ is sent to the open substack $pt = X^0 / B$. In particular, $y$ defines a $P_i \times T$-bundle together with a trivialization on $C - v$, i.e., a point of $\text{Gr}_{P_i} \times \text{Gr}_T$. This gives a map

$\mathcal{Y}_X^{\leq, \bar{\lambda}} \to \text{Gr}_{P_i} \times \text{Gr}_T.$

(7.11)

Since $X \times M_i / N_i$ is affine and $X \times M_i / N_i / (P_i \times T) \supset (X \times M_i) / (P_i \times N_i, T) = X / B$ contains $pt$ as an open substack, Lemma 3.7.3 implies that (7.11) is a closed embedding (the argument is the same as the proof of Lemma 4.1.2). Therefore at the level of reduced schemes we have a closed embedding

$(\mathcal{Y}_X^{\leq, \bar{\lambda}})_{\text{red}} \hookrightarrow \text{Gr}_{P_i}.$

We deduce that $(\mathcal{Y}_X^{\leq, \bar{\lambda}})_{\text{red}}$ is a locally closed subscheme of $(\mathcal{Y}_X^\lambda)_{\text{red}}$, since the (reduced) connected components of $\text{Gr}_{P_i}$ are locally closed subschemes of $\text{Gr}_G$. \hfill \Box

We are now ready to prove Proposition 7.3.1:
Proof of Proposition 7.3.1. Let $b \in \mathfrak{B}_{X^\star, \hat{\theta}}$. The generic point of $b \subset Y^\lambda_X$ maps to $Y^\lambda_{\hat{\theta}}$ for some $\hat{\theta} \in \mathfrak{c}^{-}_X$.

If $\hat{\theta} = 0$, then in the decomposition (7.7) we have that $b \in \mathfrak{B}_{X^\star, \lambda}$ and $\lambda = \hat{\nu}^\pm_\iota$ is the valuation attached to a color of $X^\star$. In that case, $\hat{\nu}^\pm_\iota - \hat{i}_\iota \notin \mathfrak{c}_X$, so $Y^{\lambda - \hat{i}_\iota, 0} = \emptyset$. At the same time, $b$ is a point, as recalled in §7.2.5.

Now assume $\hat{\theta} \neq 0$. As in the proof of Proposition 7.2.4, the composition $\iota_{X^\star, \hat{i}_\iota}$ sends $b$ into $S^{\lambda}_{M_t} \cap \text{Gr}^\hat{\theta}_M$; let $b_i$ be the image. By construction, $\hat{f}_i b$ either

- is zero iff $\hat{\lambda} = \hat{\theta}$, which happens precisely when $S^{\lambda}_{M_t} \cap \text{Gr}^\hat{i}_M = \{t^\hat{\theta}\}$ is closed in $\text{Gr}^\hat{i}_M$;
- or has image (under $\iota_{X^\star, \hat{i}_\iota}$) equal to an irreducible component $\hat{f}_i b_i$ of $\mathfrak{B}_i \cap S^{\lambda - \hat{i}_\iota}_{M_t}$. Indeed, this is a property of the crystal structure on MV cycles by [BG01].

In either case, the closure relations “downstairs” lift to closure relations “upstairs” under (7.10), as $b$ and $\hat{f}_i b$ get identified with the lifts of $b_i$ and $\hat{f}_i b_i$ corresponding to the same element of $\mathfrak{B}_{X^\star, \theta}$ under the identification of fibers afforded by Lemma 7.2.2. Therefore, in the first case the closure of $b$ in $Y^{\leq \lambda}_X$ is entirely contained in $Y^\lambda_X$, which by Lemma 7.3.5 means that $\mathfrak{B} \cap Y^{\lambda - \hat{i}_\iota}$ is empty; while in the second case $\hat{f}_i b$ corresponds to an irreducible component of $\mathfrak{B} \cap Y^{\lambda - \hat{i}_\iota}$.

8. Nearby cycles

8.1. Affine degeneration. There is a well-known affine family degenerating $X$ to affine closures of normal bundles in a “wonderful” compactification of $X$ (see [SV17, §2.5], [Bri07]), which closely resembles the degenerations in [Pop86], [GN10, §5.1] but lives over a different base. For the present paper we will only need the principal degeneration $X \to \mathbb{A}^1$ degenerating $X$ to a horospherical variety. This degeneration was studied by [Pop86] in characteristic 0 and [Gro92] in positive characteristic.

We have a decomposition\(^{21}\) of the ring $k[X]$ into $G$-isotypic components $k[X] = \bigoplus_{\lambda \in \mathfrak{c}^+_X} k[X]_{(\lambda)}$ where $\lambda$ denotes the highest weight of the corresponding $G$-module. In general, multiplication in $k[X]$ does not respect this grading. For any regular dominant coweight $\hat{\varrho} \in \Lambda^\lambda_G \cap \Lambda^\lambda_{\mathcal{G}^m}$, the filtration by the subspaces

$$k[X]_n := \bigoplus_{(\lambda, \hat{\varrho}) \leq n} k[X]_{(\lambda)}, \quad n \in \mathbb{N}$$

gives $k[X]$ the structure of a filtered ring ([Gro92, Lemma 7]). We will fix a choice of $\hat{\varrho}$ as above once and for all: none of our results depend on this choice.

We define the affine variety $\mathfrak{X}$ to be the spectrum of the Rees algebra associated to the above filtration: $k[\mathfrak{X}] = \bigoplus_{n \in \mathbb{N}} k[X]_n e^n$. Note that $k[\mathfrak{X}]$ contains $k[A^1] = k[e]$, so we have a $G \times \mathbb{G}_m$-morphism $\mathfrak{X} \to \mathbb{A}^1$, where $G$ acts trivially on $\mathbb{A}^1$. This forms an affine flat family ([Pop86, Proposition 9]). The fiber over $1 \in \mathbb{A}^1$ is canonically isomorphic to $X$ and the fiber over $0 \in \mathbb{A}^1$ is $X_0 := \text{Spec}(\text{gr} k[X])$. The $\mathbb{G}_m$-action on $\mathfrak{X}$ induces an isomorphism $X \times \mathbb{G}_m \cong \mathfrak{X} \times_{\mathbb{A}^1} \mathbb{G}_m$. We also have a canonical isomorphism $X / N = (X / N) \times \mathbb{A}^1$.

For $k$ of arbitrary characteristic, Grosshans showed that there is an injection

$$(8.1) \quad k[X_0] \to (k[X / N] \otimes k[N^- / G])^T$$

of $G$-algebras, which is an isomorphism if and only if $k[X]$ admits a $G$-module filtration with subquotients isomorphic to dual Weyl modules of $G$ ([Gro92, Theorems 8, 16]). Of course
this always holds in characteristic 0; in positive characteristic we will assume that (8.1) is an
isomorphism in what follows (the proofs can be easily modified to work in this case).

Let $X^\circ$ denote the preimage of $T_X \times \mathbb{A}^1 \subset X/N \times \mathbb{A}^1$ under the map $X \to X/N$. This is the
open subvariety which specializes over each fiber above $\mathbb{A}^1$ to the dense open $B$-orbit of that
fiber. Let $X^\bullet \subset X$ denote the open subvariety which specializes over each fiber to the open
$G$-orbit of that fiber.

The isomorphism (8.1) implies that $X_\emptyset$ has a natural left $T_X$-action, and the orbit of the
coset $N^{-1}$ gives an embedding $T_X \hookrightarrow X_\emptyset$. We will temporarily denote its closure by $\overline{T_X}$.

**Lemma 8.1.1.** The composition $\overline{T_X} \hookrightarrow X_\emptyset \twoheadrightarrow X_\emptyset/N = X//N$ is an isomorphism. In other
words, we have a section $X//N \hookrightarrow X_\emptyset$.

**Proof.** This is essentially a special case of [AT05, Proposition 7]. For $\lambda \in \Lambda^+_G$, the isotypic com-
ponent $k[N^{-} \backslash G]_{(\lambda)}$ is the dual Weyl module of highest weight $\lambda$. The embedding $T \hookrightarrow N^{-} \backslash G$
corresponds to the algebra map $k[N^{-} \backslash G] \to k[T]$ that sends $k[N^{-} \backslash G]_{(\lambda)} \to ke^\lambda$ (explicitly it
sends all $T$-eigenvectors not of highest weight to zero). Thus using (8.1), the map $k[X_\emptyset] \to k[T_X]$
sends $k[X_\emptyset]_{(\lambda)} \to ke^\lambda$ for $\lambda \in \mathfrak{c}_X$.

8.1.2. Contracting action. Let $s : X//N \hookrightarrow X$ denote the composition of the section given by
Lemma 8.1.1 and the embedding $X_\emptyset \hookrightarrow X$ as the zero fiber. We will construct a $\mathbb{G}_m$-action on
$X$ that contracts $X$ to the section $s$.

Recall the coweight $\hat{\varrho} : \mathbb{G}_m \to T$ used to define $X$. Let $\mathbb{G}_m$ act on $X$ via the group homomor-
phism $\mathbb{G}_m \to G \times \mathbb{G}_m : a \mapsto (\hat{\varrho}(a^{-1}), a)$ and the natural $G \times \mathbb{G}_m$-action on $X$.

**Lemma 8.1.3.** The action map $\mathbb{G}_m \times X \to X$ extends to a regular map $\mathbb{A}^1 \times X \to X$ such that
the composition $0 \times X \to \mathbb{A}^1 \times X \to X$ coincides with the composition $X \to X//N \twoheadrightarrow X$.

**Proof.** The action map can be described as the map of rings

$$k[X] \to k[\mathbb{G}_m] \otimes k[X] : f_\mu e^n \mapsto e^{n-\langle \mu, \hat{\varrho} \rangle} \otimes f_\mu e^n$$

for a $T$-eigenvector $f_\mu \in k[X]_{(\lambda)}$ of weight $\mu$. We have $\langle \mu, \hat{\varrho} \rangle \leq \langle \lambda, \hat{\varrho} \rangle \leq n$, so the image of the co-action lies in the subalgebra $k[\mathbb{A}^1] \otimes k[X]$.

Moreover, since $\hat{\varrho}$ is regular dominant, observe that $n - \langle \mu, \hat{\varrho} \rangle = 0$ if and only if $f_\mu$ is a
highest weight vector and $n = \langle \lambda, \hat{\varrho} \rangle$, which implies that the composition $0 \times X \to \mathbb{A}^1 \times X \to X$
factors through $X \\to X//N \twoheadrightarrow X$.

8.2. Grinberg–Kazhdan theorem in families. The map $X \to \mathbb{A}^1$ induces a map of formal
arc spaces $L^+ X \to L^+ \mathbb{A}^1$. Define $L^+_{\mathbb{A}^1} X = L^+ X \times \mathbb{A}^1$ where $\mathbb{A}^1 \hookrightarrow L^+ \mathbb{A}^1$ is the map of constant
arcs. Then $L^+_{\mathbb{A}^1} X$ is an affine scheme over $\mathbb{A}^1$ with fiber over $\mathbb{G}_m$ isomorphic to $L^+ X$ and zero fiber isomorphic to $L^+ X_\emptyset$. While there does not currently exist a theory of nearby cycles for
infinite type schemes, we explain below how the nearby cycles of the “IC complex” of $L^+ X$ can be modeled by nearby cycles on the global or Zastava model.

8.2.1. From now on we return to assuming that $B$ acts simply transitively on $X^\circ$, so $T_X = T$. Note that now (8.1) implies that $X_\emptyset$ is an affine embedding of $N^{-} \backslash G$.

First, we define the analogous models in families: let

$$M_X = \text{Maps}_{\text{gen}}(C, X/G \supset X^\circ/G), \quad y_X = \text{Maps}_{\text{gen}}(C, X/B \supset X^\circ/B),$$

where $X^\circ/B = \mathbb{A}^1$. Since $C$ is proper, $M_X$ maps to $\mathbb{A}^1$ with generic fiber isomorphic to $M_X$
and special fiber $M_{X_\emptyset}$. The arguments of §3 easily generalize to show that $M_X$ is an algebraic
stack locally of finite type over $\mathbb{A}^1$.\[\]
The $B$-equivariant map $\hat{x} \to X/N \times \mathbb{A}^1$ induces a map $\mathcal{Y}_X \to A \times \mathbb{A}^1$. We think of $\mathcal{Y}_X \to \mathbb{A}^1$ as a family degenerating $y = y_X$ to $y_0 := y_X$. For $\hat{x} \in \mathcal{X}$, let $y_\hat{x}$ denote the preimage of $A^\lambda$ under $\pi_X : \mathcal{Y}_X \to A$. We summarize the properties of $y_\hat{x}$ below; the proofs are easy generalizations of those for $y$.

- $y_\hat{x}$ is representable by a finite type scheme,
- $y_\hat{x}$ satisfies the graded factorization property in families, in the sense that there is a natural isomorphism
  $$y_\hat{x}^A \times (A^\lambda \times \mathbb{A}^1) \cong (y_\hat{x}^A \times y_\hat{x}^A)|_{A^\lambda \times \mathbb{A}^1}.$$
- There exists a closed embedding $y_\hat{x} \hookrightarrow \text{Gr}_{B,Sym C \times \mathbb{A}^1}$.

The models $\mathcal{M}_X, y_\hat{x}$ are smooth-locally isomorphic as families, by the following generalization of Lemma 3.5.4: Let $y_{\mathcal{X}^\bullet} = \text{Maps}_{\text{gen}}(C, \mathcal{X}^\bullet/B \supset \mathcal{X}^\circ/B)$.

**Lemma 8.2.2.** For fixed $\hat{x} \in \mathcal{X}$ and any $\mu \in \hat{x}^\text{pos}$ large enough, there is a correspondence

$$\tag{8.2} y_\hat{x}^A \leftarrow y_\hat{x}^A \times y_{\mathcal{X}^\bullet} \rightarrow \mathcal{M}_X$$

over $\mathbb{A}^1$, where the left arrow is smooth surjective and the right arrow is smooth.

The proof is the same as in loc. cit., together with the observation that $\text{Maps}(C, \mathcal{X}^\bullet/G)$ is smooth because $\mathcal{X}^\bullet/G$ is the classifying stack of a smooth group scheme over $\mathbb{A}^1$.

8.2.3. Fix an arc $\gamma_0 \in X_0(k[t]) \cap X_0^\circ(k(t))$ and consider $\gamma_0$ as a point in $L^+_A, \mathcal{X}(k)$.

**Theorem 8.2.4** (Grinberg–Kazhdan, Drinfeld). There exists a point $y \in y_0(k) \subset y_X(k)$ such that the formal neighborhood $(L^+_A, \mathcal{X})_{\gamma_0}$ is isomorphic to $\hat{\mathbb{A}}^\infty \times \hat{y}_{X,y}$.

**Proof.** Fix a point $v \in |C|$ and an identification $\mathfrak{o}_v \cong k[t]$. Note that each orbit in $X^\circ_0(F_v)/G(\mathfrak{o}_v)$ has a representative in $X^\circ_0(F_v)$. Thus by $G(\mathfrak{o}_v)$-translation we may assume that $\gamma_0 \in X_0(\mathfrak{o}_v) \cap X^\circ_0(\mathfrak{F}_v)$. We may consider $\gamma_0$ as a section $\text{Spec} \mathfrak{o}_v \to X_0 \times_B \mathfrak{P}_B$ where $\mathfrak{P}_B$ is the trivial $B$-bundle on $\text{Spec} \mathfrak{o}_v$. By Lemma 3.7.7, this is equivalent to a map $y : C \to X_0/B$ with $y(C - v) = \mathfrak{pt}$. This is the point $y \in y_0(k)$ we will use.

Next, we define a map of formal schemes

$$\tag{8.3} (L^+_A, \mathcal{X})_{\gamma_0} \rightarrow \hat{y}_{X,y}$$

as follows: Formal schemes are determined by their $R$-points where $R$ is a local commutative $k$-algebra with residue field $k$ whose maximal ideal $m$ is nilpotent. Let $\gamma : \text{Spec} R[t] \rightarrow \mathcal{X}$ be an $R$-point of $(L^+_A, \mathcal{X})_{\gamma_0}$. The reduction modulo $m$ of $\gamma|_{\text{Spec} R(t)}$ equals $\gamma_0|_{\text{Spec} k(t)} \in \mathfrak{X}^\circ(k(t))$. Since $k((t))$ is the unique closed point of $R((t))$, we deduce that $\gamma|_{\text{Spec} R(t)}$ has image contained in $\mathfrak{X}^\circ$. Consider $\gamma$ as a section $\text{Spec}(R \otimes \mathfrak{o}_v) \rightarrow \mathcal{X} \times_B \mathfrak{P}_B$ where $\mathfrak{P}_B$ is the trivial $B$-bundle. By an easy generalization of Lemma 3.7.7, the pair $(\mathfrak{P}_B, \gamma)$ is equivalent to a map $\tilde{y} : C \times \text{Spec}(R) \rightarrow \mathcal{X}/B$ such that $\tilde{y}|(C - v) \times \text{Spec}(R)$ factors through $\text{Spec}(R) \rightarrow \mathbb{A}^1 = \mathfrak{X}^\circ/B$. We define (8.3) on $R$-points by sending $\gamma \mapsto \tilde{y}$.

Since $(L^+_B)$ is non-canonically isomorphic to $\hat{\mathbb{A}}^\infty$, the theorem follows from the proposition below.

**Proposition 8.2.5.** Let $y : C \to X_0/B$ satisfy $y(C - v) = \mathfrak{pt}$ and $y|_{\text{Spec} \mathfrak{o}_v}$ corresponds to $(\mathfrak{P}_B, \gamma_0)$. Then the map (8.3) is a $(L^+_B)$-torsor.
Proof. Let \((R, m)\) as above. By a generalization of Lemma 3.7.7, an \(R\)-point of \(\hat{\mathfrak{U}}_{X, y}\) is equivalent to a map \(\tilde{\gamma} : \text{Spec } R[t] \to \mathfrak{X}/B\) such that \(\tilde{\gamma}|_{\text{Spec } R(t)}\) factors through \(\text{Spec } R \to \mathbb{A}^1\). Their restrictions to \(\text{Spec } R(t)\) are isomorphic. The fiber of (8.3) over \(\tilde{\gamma}\) parametrizes maps \(\gamma : \text{Spec } R[t] \to \mathfrak{X}\) that induce \(\tilde{\gamma}\) and whose reduction modulo \(m\) equals \(\gamma_0\). Since any \(B\)-bundle on \(\text{Spec } R[t]\) can be trivialized, we see that \((L+B)_1(R)\) acts simply transitively on this fiber, since \(\gamma_0 \in X^0_R(k(t)) \cong B(k(t))\). \(\square\)

8.3. Results on nearby cycles. We will now consider nearby cycles on the global and Zastava models.

8.3.1. Fix \(\lambda \in \mathfrak{c}_X\) and consider the family \(f : \mathfrak{y}_X^\lambda \to \mathbb{A}^1\). We have complementary embeddings

\[
y^\lambda_0 : \mathfrak{y}_X^\lambda \hookrightarrow \mathfrak{y}_X^\lambda \times \mathbb{G}_m
\]

where \(i, j\) correspond to \(f^{-1}(0), f^{-1}(\mathbb{G}_m)\), respectively.

We have the usual (unshifted) nearby cycles functor \(\psi_f : D_c^b(\mathfrak{y}_X^\lambda \times \mathbb{G}_m) \to D_c^b(\mathfrak{y}_0^\lambda)\) as defined in [SGA73, Exposé XIII], so \(\psi_f[-1]\) is t-exact with respect to the perverse \(t\)-structure. Let

\[
\Psi_y = \psi_y[-1] : P(\mathfrak{y}_X^\lambda \times \mathbb{G}_m) \to P(\mathfrak{y}_0^\lambda)
\]

denote the direct factor where the monodromy operator acts unipotently.

In this section we will compute \(\Psi_y(\mathbb{IC}_{\mathfrak{y}_X^\lambda \times \mathbb{G}_m}) \in P(\mathfrak{y}_0^\lambda)\) in terms of \(\mathfrak{ic}_{\mathfrak{y}_0^\lambda}\). More specifically, we only compute the image \([\Psi_y(\mathbb{IC}_{\mathfrak{y}_X^\lambda \times \mathbb{G}_m})]\) in the Grothendieck group; we do not describe the monodromy action in this paper, but we believe our results can be used to give a description of the associated graded \(\mathfrak{gr} \Psi_y(\mathbb{IC}_{\mathfrak{y}_X^\lambda \times \mathbb{G}_m})\) of the monodromy filtration in terms of Picard–Lefschetz oscillators along the lines of [Cam18, Theorem 1.4.1].

Remark 8.3.2. Since \(\mathfrak{X}\) has a \(\mathbb{G}_m\)-action making \(f\) equivariant and \(\mathbb{IC}_{\mathfrak{y}_X^\lambda \times \mathbb{G}_m}\) is \(\mathbb{G}_m\)-equivariant, a standard argument ([AB09, Remark 14]) shows that \(\psi_f(\mathbb{IC}_{\mathfrak{y}_X^\lambda \times \mathbb{G}_m}) = \psi_f(\mathbb{IC}_{\mathfrak{y}_X^\lambda \times \mathbb{G}_m})\), i.e., the monodromy is unipotent.

There is an analogous global family \(\mathcal{M}_X \to \mathbb{A}^1\) and complementary embeddings

\[
\mathcal{M}_{X_0} \hookrightarrow \mathcal{M}_X \hookrightarrow \mathcal{M}_X \times \mathbb{G}_m.
\]

Denote the associated unipotent nearby cycles functor by \(\Psi_{\mathcal{M}} : P(\mathcal{M}_X \times \mathbb{G}_m) \to P(\mathcal{M}_{X_0})\). We will simultaneously compute \([\Psi_{\mathcal{M}}(\mathbb{IC}_{\mathcal{M}_X \times \mathbb{G}_m})]\).

8.3.3. Stratifications in the horospherical case. Before proceeding, we give a more concrete description of the stratifications on \(\mathfrak{y}_0^\lambda, \mathcal{M}_{X_0}\) using (8.1).

Since \(\mathfrak{T}_X = T\), we have \(X_{0}^* = N^*-G\) and \(\mathcal{M}_{X_0}^* = \text{Bun}_{N^*}\). The isomorphism (8.1) induces a map of affine schemes \(X_0//N \times T^* \to G^* \to X_0\), which in turn induces a map of stacks

\[
\tilde{\iota}_M : \mathcal{A} \times \text{Bun}_{N^*} \to \mathcal{M}_{X_0}^*.
\]

Let \(\iota_M : \mathcal{A} \times \text{Bun}_{N^*} \to \mathcal{M}_{X_0}\) denote the restriction. For \(\lambda \in \mathfrak{c}_X\), let \(\tilde{\iota}_M^\lambda, \iota_M^\lambda\) denote the maps corresponding to \(A^\lambda\). The following is a variant of [BG02, Proposition 1.2.7], whose proof we leave to the reader.

Proposition 8.3.4. The map \(\tilde{\iota}_M^\lambda\) is finite, and its restriction \(\iota_M^\lambda\) is a locally closed embedding.
The subschemes \( \mathcal{M}_{\lambda}^{\mu} = \iota_{M}^{*}(A^\lambda \times \text{Bun}_T \text{Bun}_B^-) \) for \( \lambda \in \mathcal{C} \) form a (possibly non-smooth) stratification of \( \mathcal{X} \). This is a coarser stratification than the one defined in §3.1.5 in the following sense: Note that \( \mathcal{V}(X_\emptyset) = \mathcal{X} \) so \( \mathcal{C} = \mathcal{X} \). For a partition \( \Psi \in \text{Sym}^\infty(\mathcal{C} \setminus 0) \), there is a locally closed embedding \( \mathcal{C}^\Psi \hookrightarrow A^{\deg(\Psi)} \), and the collection of these subschemes ranging over all partitions \( \Psi \) with \( \deg(\Psi) = \lambda \) forms a smooth stratification of \( A^\lambda \). It follows from the constructions that the strata from §3.1.5 are given by

\[
\mathcal{M}_{\lambda}^{\Psi} \cong \mathcal{C}^\Psi \times _{\text{Bun}_T} \text{Bun}_B^- \cong \mathcal{C}^\Psi \times _{A^{\deg(\Psi)}} \mathcal{M}_{\lambda}^{\deg(\Psi)}
\]

indexed over all \( \Psi \in \text{Sym}^\infty(\mathcal{C} \setminus 0) \).

Next if we consider the corresponding Zastava model, we have

\[
y_\emptyset^\lambda = \mathcal{Z}_{\emptyset,0} = \text{Maps}(C, N^- \setminus G/B \ni \text{pt})
\]

is the \textit{open Zastava space} of Finkelberg–Mirković. The \textit{Zastava space} \(^{22}\) is in turn defined by \( \mathcal{Z} = \text{Maps}_{\text{gen}}(C, N^- \setminus G/B \ni \text{pt}) \). The geometry of the Zastava space has been extensively studied in [FM99, FFKM99, BFGM02]. The components of \( \mathcal{Z} \) are indexed by \( \Lambda^\text{pos}_G \).

We can also define the relative open Zastava space \( \mathcal{Z}_{\text{Bun}_T}^{\emptyset,0} = \text{Maps}_{\text{gen}}(C, B^- \setminus G/B \ni \text{pt}/T) \). The spaces \( \mathcal{Z}_{\emptyset,0} \) and \( \mathcal{Z}_{\text{Bun}_T}^{\emptyset,0} \) are smooth locally isomorphic (cf. [BFGM02, §3.1]). For \( \lambda \in \Lambda^\text{pos}_G \), let \( \mathcal{Z}_{\text{Bun}_T}^{\lambda,0} \) denote the preimages of \( \text{Bun}_T^\mu \times \text{Bun}_B^{-\lambda} \) running over all \( \mu \in \Lambda_G^\text{pos} \).

Since \( y_\emptyset \) is open in \( \mathcal{M}_{\lambda}^{\mu} \times \text{Bun}_B \), we deduce by base change that for any \( \lambda \in \mathcal{C} \), \( \mu \in \Lambda^\text{pos}_G \), there is a locally closed embedding

\[
i_{\lambda,0}^{\lambda,\mu} : A^\lambda \times _{\text{Bun}_T} \mathcal{Z}_{\text{Bun}_T}^{\emptyset,0} \rightarrow y_{\emptyset}^\lambda
\]

where we are mapping \( \mathcal{Z}_{\text{Bun}_T}^{\emptyset,0} \rightarrow \text{Bun}_B^- \rightarrow \text{Bun}_T \). Note that \( \mathcal{Z}_{\text{Bun}_T}^{\emptyset,0} = \text{Bun}_T \), so \( \ni_{\lambda,0}^{\lambda,\mu} \) defines a map \( A^\lambda \hookrightarrow y_{\emptyset}^\lambda \). One can check that this map corresponds to applying Maps(\( C, T \),\(^?\)) to the section \( s_\emptyset : X/N \rightarrow X_\emptyset \) from Lemma 8.1.1. Therefore

\[
y^\lambda_\emptyset := \ni_{\lambda,0}^{\lambda,\mu} : A^\lambda \rightarrow y_{\emptyset}^\lambda
\]

is a section of the projection \( \pi_\emptyset : y_{\emptyset}^\lambda \rightarrow A^\lambda \).

8.3.5. We compute the \( *\)-restriction of nearby cycles to the strata above, which suffices to determine nearby cycles in the Grothendieck group. Let \( \Omega(\tilde{n}_C)^{-\nu} = \mathbb{D} \Gamma(\tilde{n}_C)^{\mu} \) denote the Verdier dual of the factorization algebra defined in §4.5. The statement of our main result is:

**Theorem 8.3.6.** We have equalities in the Grothendieck group

\[
[\Psi_{\mathcal{M}}(IC_{\mathcal{M} \times G_m})] = \sum_{\lambda \in \mathcal{C}} \sum_{\nu \geq 0} \left[ \iota_{\mathcal{M},!}^{\lambda} \left( \left( i_A, \delta_{\lambda, \nu}(\Omega(\tilde{n}_C)^{-\nu}) * \pi_\emptyset^{\lambda}(IC_{\mathcal{Y}^\lambda, \emptyset}) \right) \boxtimes _{\text{Bun}_T} IC_{\text{Bun}_B^-} \right) \right]
\]

\[
[\Psi_{\mathcal{Y}}(IC_{\mathcal{Y}^{\mu} \times G_m})] = \sum_{\lambda \in \mathcal{C}} \sum_{\nu \geq 0} \left[ \iota_{\mathcal{Y},!}^{\mu, -\lambda} \left( \left( i_A, \delta_{\mu, \nu}(\Omega(\tilde{n}_C)^{-\nu}) * \pi_\emptyset^{\mu}(IC_{\mathcal{Y}^{\mu - \lambda}, \emptyset}) \right) \boxtimes _{\text{Bun}_T} IC_{\mathcal{Z}^{\mu - \lambda, 0}_{\text{Bun}_T}} \right) \right]
\]

for any \( \mu \in \mathcal{C} \) in the second equality.

\(^{22}\)The Finkelberg–Mirković Zastava space is the Zastava model for \( G/N \). In this paper we made a slight distinction in semantics between ‘model’ and ‘space’ to avoid confusion, but the two terms are interchangeable.
We point out that the description of $\tilde{\pi}_! IC_{y, X}$ is the main content of this paper. In particular it has the format (6.12).

Recall that $\mathcal{F} \boxtimes \mathcal{G}$ denotes the $*$-restriction of $\mathcal{F} \boxtimes \mathcal{G}$ to the corresponding fiber product over $\text{Bun}_T$, shifted by $[-\dim \text{Bun}_T]$. Note that $\text{Bun}_B$ and $\mathbb{Z}^{2,0}_{\text{Bun}_T}$ are smooth stacks, so the respective IC complexes are shifted constant sheaves.

**Proof.** Theorem 8.3.6 follows by combining Corollary 4.5.7 with Lemma 8.3.7 and Proposition 8.3.8 below. □

First, a well-known argument using some Zastava-to-global yoga allows us to reduce from computing restrictions to all strata to only computing $s_\lambda^{\bar{\lambda}} \Psi_M IC_{y, X}$ for all $\lambda \in \mathcal{A}_G$.

**Lemma 8.3.7.** We have equalities in the Grothendieck group\(^{23}\)

\[
\begin{align*}
(8.4) & \quad [\ell_M^{\bar{\lambda}} \Psi_M IC_{\text{M}_X \times \mathcal{G}_m}] = [\ell_0^{\bar{\lambda}} \Psi_M IC_{\text{Bun}_B - \text{M}_{\text{Bun}_T}}] \\
(8.5) & \quad [\ell_0^{\bar{\lambda}} \Psi_M IC_{\text{Bun}_B - \text{M}_{\text{Bun}_T}}] = [\ell_0^{\bar{\lambda}} \Psi_M IC_{\text{Bun}_B - \text{M}_{\text{Bun}_T}}],
\end{align*}
\]

where $\lambda, \bar{\lambda} \in \mathcal{A}_G$, $\mu, \bar{\mu} \in \mathcal{A}_G^{\text{pos}}$.

**Proof.** The argument is the same as [BFGM02, §3.1, §8(1)] and [BG08, Proof of Proposition 4.4]. The strategy is that we first show (8.4) and then use it to show (8.5).

Fix $\bar{\lambda} \in \mathcal{A}_G$ and $\mu, \bar{\mu} \in \mathcal{A}_G^{\text{pos}}$ large enough as in Lemma 8.2.2 and consider the correspondence (8.2). The fiber of (8.2) over 0 $\in \mathbb{A}^1$ gives the correspondence

\[
\begin{aligned}
y_0^{\bar{\lambda}} & \leftarrow y_0^{\bar{\lambda}} \times \mathbb{Z}^{\bar{\mu}, 0} \rightarrow \mathcal{M}_Y.
\end{aligned}
\]

Since nearby cycles commute with smooth base change of the family over $\mathbb{A}_G$, we deduce that there is an isomorphism

\[
\Psi_M IC_{\text{Bun}_B - \text{M}_{\text{Bun}_T}} IC_{\text{Bun}_B - \text{M}_{\text{Bun}_T}^{\text{pos}}}.
\]

We now restrict to strata: for $\lambda \in \mathcal{A}_G$ observe that there is a commutative diagram where both squares are Cartesian

\[
\begin{array}{ccc}
\mathcal{A}_G^{\lambda} \times \mathbb{Z}^{\lambda - \lambda, 0}_{\text{Bun}_T} & \leftarrow & (\mathcal{A}_G^{\lambda} \times \mathbb{Z}^{\lambda - \lambda, 0}_{\text{Bun}_T}) \times \mathbb{Z}^{\bar{\mu}, 0} \rightarrow \mathcal{A}_G^{\lambda} \times \mathbb{Z}^{\bar{\mu}, 0} \\
\downarrow & & \downarrow \\
y_0^{\lambda} \leftarrow y_0^{\lambda} \times \mathbb{Z}^{\bar{\mu}, 0} \rightarrow \mathcal{M}_Y
\end{array}
\]

By the argument of [BFGM02, §8(1)], every point of $\mathcal{A}_G^{\lambda} \times \mathbb{Z}^{\bar{\mu}, 0}$ is in the image of $y_0^{\lambda} \times \mathbb{Z}^{\bar{\mu}, 0}$ for some $\bar{\mu}$ large enough, i.e., we only need to consider the diagram (8.7) when $\lambda = \bar{\lambda}$. Note that $\mathcal{A}_G^{\lambda} \times \mathbb{Z}^{\bar{\mu}, 0}$ is of finite type, so there exists a single $\bar{\mu}$ such that the map $y_0^{\lambda} \times \mathbb{Z}^{\bar{\mu}, 0} \rightarrow \mathcal{M}_Y$ has geometrically irreducible fibers and contains $\mathcal{A}_G^{\lambda} \times \mathbb{Z}^{\bar{\mu}, 0}$ in its image (Corollary 3.5.2). In particular, pullback along this map is fully faithful on perverse sheaves.

By restricting the isomorphism (8.6) to the stratum $\mathcal{A}_G^{\lambda} \times \mathbb{Z}^{\bar{\mu}, 0}$, we get

\[
s_\lambda^{\bar{\lambda}} \Psi_M IC_{\text{Bun}_B - \text{M}_{\text{Bun}_T}} IC_{\text{Bun}_B - \text{M}_{\text{Bun}_T}^{\text{pos}}}.
\]

\(^{23}\)In fact the isomorphisms hold in the derived category, but we omit the proof as it uses generic-Hecke equivariance to show no twist exists on the $\text{Bun}_B$ factor.
This establishes the equality (8.4) in the Grothendieck group by fully faithfulness of the pullback.

The equality (8.5) follows from (8.4) and (8.6) in the same fashion by considering the diagram (8.7) with $\lambda' = \lambda + \check{\nu}$. □

Define the functor $\Psi : P(Y^\lambda) \to P(Y^\lambda_0)$ by $\Psi(F) = \Psi_y(F \boxtimes IC_{G_m})$. The crucial fact that will allow us to do our computations is the following:

**Proposition 8.3.8.** There are natural isomorphisms of functors $D^b_\lambda(Y^\lambda) \to D^b_\lambda(A^\lambda)$:

\[ s^{\lambda, *}_0 \Psi \cong \pi_{0, *}' \Psi \cong \pi_*, \]

\[ s^{\lambda, !}_0 \Psi \cong \pi_{0, !}' \Psi \cong \pi_i. \]

The proposition will be proved using a standard argument involving the contraction principle.

As explained in the introduction, the functors $\pi_!, \pi_{0, !}$ correspond to Radon transforms on $X^*(F), X^*_Y(F)$, respectively, under the functions–sheaves dictionary. Thus the isomorphism $\pi_{0, !}' \Psi \cong \pi_!$ is a categorification of the relation between asymptotics $e^\alpha_0$ and Radon transform ([SV17, Proposition 5.4.6]). Since the Radon transform for $X^*_Y(F) = (N^- \setminus G)(F)$ is in an appropriate sense invertible by the theory of intertwining operators, this also shows that $\Psi$ indeed corresponds to $e^\alpha_0$ under the functions–sheaves dictionary.

8.4. **Contraction principle.** Set $s^\lambda = i \circ \iota^\lambda : A^\lambda \to Y^\lambda_X$. We drop the superscript to denote the section $s : A \hookrightarrow Y_X$ on all components. Recall that $s$ corresponds to the map induced by the embedding $s : X/G \to X$, and Lemma 8.1.3 defines an action of $A^1$ on $X$ that contracts to $s$. The action of $A^1$ commutes with that of $G$, so we get an action $A^1 \times Y_X \to Y_X$ such that $0 \times Y_X \to Y_X$ coincides with $s \circ \pi_X$. In this situation, the **contraction principle** ([BF02, Lemma 5.3], [Laf, Lemme 2.2], which is closely related to Braden’s theorem [Bra03]) says that there is a natural isomorphism of functors $\pi_{X,*} \cong \iota_* : D^b_\lambda(Y_X) \to D^b_\lambda(A)$.

**Proof of Proposition 8.3.8.** We will prove the first line of isomorphisms; the second line follows from the first by Verdier duality. If we apply the contraction principle to $s^{\lambda, *}_0 \Psi = \iota^{\lambda, !}_* \Psi$, we immediately get the first isomorphism $s^{\lambda, *}_0 \Psi \cong \pi_{0, *}' \Psi$.

Next, we will show the isomorphism $s^{\lambda, !}_0 \Psi \cong \pi_*$. Recall that [Bei87b] gives an equivalence $D^b P(Y^\lambda) \cong D^b_\lambda(Y^\lambda)$, so we only need to define the isomorphism on perverse sheaves. Let $\mathcal{F} \in P(Y^\lambda)$. For any $a \geq 1$, let $\mathcal{L}_a$ denote the local system on $G_m$ whose monodromy is a unipotent Jordan block of rank $a$. There are canonical injections $\mathcal{L}_a \to \mathcal{L}_{a+1}$. Beilinson’s construction of the unipotent nearby cycles functor $\Psi_y$ (cf. [Bei87a, 2.3]) gives an isomorphism

\[ \Psi(\mathcal{F}) \cong \text{colim}_{a \geq 1} i^* j_{a,*}(\mathcal{F} \boxtimes \mathcal{L}_a). \]

We can further apply $s^{\lambda, *}_0$ to get an isomorphism $s^{\lambda, *}_0 \Psi(\mathcal{F}) \cong \text{colim}_{a \geq 1} s^{\lambda, *}_0 j_{a,*}(\mathcal{F} \boxtimes \mathcal{L}_a)$. Applying the contraction principle, we get an isomorphism

\[ s^{\lambda, *}_0 \Psi(\mathcal{F}) \cong \text{colim}_{a \geq 1} (\pi_{X} \circ j)_a(\mathcal{F} \boxtimes \mathcal{L}_a). \]

Note that $\pi_X \circ j : Y \times G_m \to A$ is equal to the composition of the first projection $Y \times G_m \to Y$ and $\pi : Y \to A$. Therefore

\[ (\pi_X \circ j)_a(\mathcal{F} \boxtimes \mathcal{L}_a) = \pi_* (\mathcal{F} \boxtimes \mathcal{L}_a) \otimes H^*(G_m, \mathcal{L}_a). \]

Since $\text{colim}_{a \geq 1} H^*(G_m, \mathcal{L}_a) = \overline{Q}_0$, we conclude that $s^{\lambda, *}_0 \Psi(\mathcal{F}) \cong \pi_* (\mathcal{F})$. □
Appendix A. Properties of the global stratification

A.1. The factorizable space of formal loops. We briskly review the definitions of multipoint versions of the spaces of formal arcs and formal loops. We refer the reader to [KV04], [Zhu17, §3.1] for a more complete account.

Let \( C \) be a smooth curve over \( k \). For any \( N \in \mathbb{N} \), we have the \( N \)th symmetric product \( C^{(N)} \) of \( C \), which identifies with the Hilbert scheme \( \text{Hilb}^N(C) \) parametrizing relative effective divisors in \( C \) of degree \( N \).

Recall that if \( S \) is an affine scheme and \( D \subset C \times S \) is a closed affine subscheme, we denote by \( \tilde{C}_D \) the spectrum of the ring of regular functions on the formal completion of \( C \times S \) along \( D \) (so \( \tilde{C}_D \) is a true scheme, not merely a formal scheme). Let \( \tilde{C}_D' := \tilde{C}_D - D \) denote the open subscheme.

For any \( k \)-scheme \( X \), we define the global space of formal arcs by the functor

\[
(\mathcal{L}^{+}X)_{C^{(N)}}(S) = \{ D \in C^{(N)}(S), \gamma \in X(\tilde{C}_D') \},
\]

for affine test schemes \( S \). By [KV04, Proposition 2.4.1], the functor \( (\mathcal{L}^{+}X)_{C^{(N)}} \) is representable by a scheme of infinite type over \( C^{(N)} \). If \( X \) is affine, then \( (\mathcal{L}^{+}X)_{C^{(N)}} \) is affine over \( C^{(N)} \), cf. [KV04, 2.4.3]. More specifically, define the space of \( n \)-jets \( (\mathcal{L}_n^{+}X)_{C^{(N)}} \) by

\[
(\mathcal{L}_n^{+}X)_{C^{(N)}}(S) = \{ D \in C^{(N)}(S), \gamma \in X(\tilde{C}_D^n) \},
\]

where \( \tilde{C}_D^n \) denotes the \( n \)th infinitesimal neighborhood of \( D \) in \( C \times S \). Then \( (\mathcal{L}_n^{+}X)_{C^{(N)}} \) is representable by a scheme over \( C^{(N)} \), which is affine (resp. of finite type) if \( X \) is. As \( n \) varies the schemes \( (\mathcal{L}_n^{+}X)_{C^{(N)}} \) form a projective system of schemes with affine transition maps, and \( (\mathcal{L}^{+}_{C^{(N)}}X)_{C^{(N)}} \) is equal to the projective limit of this system. If \( X \) is smooth, the schemes \( (\mathcal{L}_n^{+}X)_{C^{(N)}} \) are smooth over \( C^{(N)} \) with smooth surjective transition maps (cf. [Ras, Lemma 2.5.1]).

We can also define the functor for the global loop space by

\[
(\mathcal{L}X)_{C^{(N)}}(S) = \{ D \in C^{(N)}(S), \gamma \in X(\tilde{C}_D^{o}) \}.
\]

If \( X \) is affine, then \( (\mathcal{L}X)_{C^{(N)}} \) is representable by an ind-scheme ind-affine over \( C^{(N)} \), cf. [KV04, Proposition 2.5.2]. We have a closed embedding \( (\mathcal{L}^{+}X)_{C^{(N)}} \hookrightarrow (\mathcal{L}X)_{C^{(N)}} \).

A.1.1. We can think of \( (\mathcal{L}^{+}X)_C, (\mathcal{L}X)_C \) as twisted products

\[
(\mathcal{L}^{+}X)_C = C \times L^+X, \quad (\mathcal{L}X)_C = C \times LX,
\]

where \( C \times L^+X := C^\wedge \times ^{\text{Aut} k[t]} L^+X \) and \( C^\wedge \rightarrow C \) is the \( \text{Aut} k[t] \)-torsor classifying \( v \in C \) together with an isomorphism \( o_v \cong k[t] \).

Remark A.1.2. The space \( \mathcal{L}X \) really lives over the Ran space of \( C \). Essentially this just means \( \mathcal{L}X \) only cares about the support of the divisor \( D \) and not its multiplicities. More specifically for any finite set \( I \) we have a map \( C^I \rightarrow C^{(|I|)} \) where \( |I| \) denotes the cardinality of \( I \). Then the spaces \( (\mathcal{L}X)_{C^I} := C^I \times _{C^{(|I|)}} (\mathcal{L}X)_{C^{(|I|)}} \) have a factorization monoid structure as defined in [KV04, Definition 2.2.1], and we can think of the collection of these spaces as \( (\mathcal{L}X)_{\text{Ran} C} \). This is certainly the more philosophically correct approach to considering the loop space, but for technical simplicity it will suffice for our study of arc spaces to work with \( \mathcal{L}^{+}X \) over \( \text{Sym} C \).

A.1.3. We can apply the above constructions to the algebraic group \( G \). Since \( G \) is smooth, \( \mathcal{L}^{+}G \) is a group scheme formally smooth over \( \text{Sym} C \).

Consider the (factorizable) Beilinson–Drinfeld affine Grassmannian \( \text{Gr}_{G,\text{Sym} C} \) defined in §3.7. By Beauville–Laszlo’s theorem (see [BD96, Remark 2.3.7], [Zhu17, Proposition 3.1.9]), we have an isomorphism \( \text{Gr}_{G,\text{Sym} C} \cong \mathcal{L}G/\mathcal{L}^{+}G \).
A.1.4. Let $X$ be an affine spherical $G$-variety. Define

$$L^\bullet X := L X - L(X - X^\bullet),$$

which admits an open embedding into $L X$. The $G$-action on $X$ induces a natural action of $L G$ on $L X$ and the subspace $L^\bullet X$ (resp. $L^+ X$) is stable under the action of $L G$ (resp. $L^+ G$).

We will primarily be concerned with the global space of non-degenerate arcs

$$(L^+ X)^\bullet := L^+ X \times_{L X} L^\bullet X.$$ 

The study of the loop space $L^\bullet X$ is beyond the scope of this paper.

A.2. Multi-point orbits. We now consider the $L^+ G$-orbits on $(L^+ X)^\bullet$, and we will prove a multi-point version of Proposition 2.2.6.

A.2.1. What is going on at the level of $k$-points. A $k$-point of $\text{Ran}_C$ is a nonempty finite subset $\{v_i \in |C|\}_{i \in I}$ of points on $C$. Then a $k$-point of $(L^+ X)^\bullet_{\text{Ran}_C}$ over $\{v_i\}$ consists of points $x_i \in X(\alpha_v) \cap X^*(F_v)$, where all but finitely many $x_i$ are distinct. Using the factorization property, we can define a closed embedding

$$(L^+ X)^\bullet := L^+ X \times_{L X} L^\bullet X.$$ 

Therefore the tuple $(x_i)_{i \in I}$ is a $k$-point in the product of orbits $\prod_{i \in I} L^+_v X$.

The idea for what follows is that this product of orbits only depends on the unordered multiset $\{\theta_i\}$, counted with multiplicity. Moreover since $G_0$ is a strictly convex cone, the set of formal sums $\sum f \cdot v_i$ admits a positive grading.

A.2.2. Construction. Let $\hat{\Theta}_0$ denote an (unordered) multiset in $\mathfrak{c}_X$, by which we mean a formal sum

$$\sum_{\theta \in \mathfrak{c}_X} N_{\theta} \hat{\theta} \in \text{Sym}^\infty(\mathfrak{c}_X)$$

where all but finitely many $N_{\hat{\theta}} = 0$. Note that we include the case $\hat{\theta} = 0$ and $N_0$ may be nonzero. See §3.1.4 for notation.

A $k$-point of $\tilde{C}^\hat{\Theta}_0$ is a finite nonempty subset $\{v_i\}_{i \in I}$ of $C(k)$ and assignments $i \mapsto \hat{\theta}_i$, such that $\hat{\Theta}_0 = \sum_{i \in I} [\hat{\theta}_i]$ as a formal sum, i.e., the multiset $\{\hat{\theta}_i\}$ coincides with $\hat{\Theta}_0$ with multiplicities. In particular, $|I| = |\hat{\Theta}_0|$. We have an étale map $\tilde{C}^\hat{\Theta}_0 \to \tilde{C}^\hat{\Theta}_0(1,0) \subset \text{Sym} C$ by sending $\sum_i \hat{\theta}_i \cdot v_i$ to $\sum_i v_i$, where all $v_i$ are distinct. Using the factorization property, we can define a closed embedding

$$\tilde{C}^\hat{\Theta}_0 \hookrightarrow \tilde{C}^\hat{\Theta}_0 \times_{\text{Sym} C} L^+ X =: (L^+ X)_{\tilde{C}^\hat{\Theta}_0}$$

sending $\sum_i \hat{\theta}_i \cdot v_i \mapsto (x_0 \cdot t^\hat{\theta}_i \in L^+_v X)_{i \in I}$.

Composing the above with the action map $L^+ X \times_{\text{Sym} C} L^+ G \to L^+ X$ gives a map

$$\Gamma_{\hat{\Theta}_0} : \tilde{C}^\hat{\Theta}_0 \times_{\text{Sym} C} L^+ G \to \tilde{C}^\hat{\Theta}_0 \times_{\text{Sym} C} L^+ X.$$ 

Define $L^\Theta_0 X$ to be the image of $\Gamma_{\hat{\Theta}_0}$, given the reduced scheme structure.

Proposition A.2.3. The scheme $L^\Theta_0 X$ is formally smooth over $\tilde{C}^\hat{\Theta}_0$, and second projection induces a locally closed embedding $L^\Theta_0 X \to L^+ X$.

Proof. We first prove everything for finite jets and then take the projective limit. We have a map $\tilde{C}^\hat{\Theta}_0 \to L^+_n X$ for any $n \in \mathbb{Z}_{\geq 0}$, defined just as in (A.1), which induces an orbit map

$$\Gamma_{\hat{\Theta}_0, n} : \tilde{C}^\hat{\Theta}_0 \times_{\text{Sym} C} L^+_n G \to \tilde{C}^\hat{\Theta}_0 \times_{\text{Sym} C} L^+_n X =: (L^+_n X)_{\tilde{C}^\hat{\Theta}_0}$$
between schemes of finite type over \( k \), where \( \Theta_0 = \sum \theta_i \). Denote by \( \mathcal{L}_{\Theta_0}^* X \) the image of this map and by \( Y \) its reduced closure in \( (\mathcal{L}_{\Theta_0}^* X)_{\Theta_0} \). Let \( N = |\Theta_0| := \sum \theta_i \).

There is an étale map \( \hat{C}^N \to \hat{C}^{\Theta_0} \). Thus to show that \( \mathcal{L}_{\Theta_0}^* X \) is smooth over \( \hat{C}^{\Theta_0} \) and open in \( Y \), it suffices to show this after base change to \( \hat{C}^N \). By factorization, the base change of \( \mathcal{L}_{\Theta_0}^* X \) to \( \hat{C}^N \) identifies with the \( N \)-fold disjoint product of \( C \times L_\theta^N X \), with \( \theta \) appearing \( N \) times in the product; the twisted product \( \hat{X} \) is as in \S A.1.1. Now \( L_\theta^N X \) is smooth and open in its closure by the proof of Proposition 2.2.6.

It remains to show that the second projection \( \pi_2 : (\mathcal{L}_{\Theta_0}^* X) \to L_\theta^N X \) is a locally closed embedding. This is the base change of the étale map \( \hat{C}^{\Theta_0} \to \hat{C}^N \subseteq C \). Therefore \( \pi_2 \) is the composition of the finite étale map

\[
\mathcal{L}_{\Theta_0}^* X \to (\mathcal{L}_{\Theta_0}^* X)_{\overline{C}(N)} := \hat{C}^N \times_{\overline{C}} L_\theta^N X
\]

and the open embedding \( (\mathcal{L}_{\Theta_0}^* X)_{\overline{C}(N)} \hookrightarrow \hat{C}^N X \). Hence it suffices to show that the restriction \( \mathcal{L}_{\Theta_0}^* X \subseteq (\mathcal{L}_{\Theta_0}^* X)_{\overline{C}(N)} \to (\mathcal{L}_{\Theta_0}^* X)_{\overline{C}(N)} \) is locally closed. Observe that \( \mathcal{L}_{\Theta_0}^* X = \pi_2^{-1}(\mathcal{L}_{\Theta_0}^* X) \) for \( n \gg 0 \). Therefore \( Y' = \pi_2^{-1}(Y) \) is a closed subscheme of \( (\mathcal{L}_{\Theta_0}^* X)_{\overline{C}(N)} \) and \( \pi_2^* \) restricts to an étale map \( \hat{C}^{\Theta_0} \to \pi_2^{-1}(Y') \to Y' \) which is injective on \( k \)-points. Therefore it is an open embedding.

It is easy to see that the transition maps \( \mathcal{L}_{\Theta_0}^* X \to \mathcal{L}_{\Theta_0}^* X \) are affine, and taking the projective limit, we finish the proof of the proposition. \( \square \)

A.3. Proof of Lemma 3.1.6. Assume that \( C \) is complete. Let \( (M_X \times \text{Sym} C)^{\ast} \) denote the substack of \( M_X \times \text{Sym} C \) consisting of those pairs \((f, D)\) where \( f(C - D) \subseteq X^* / G \), i.e., \( C - D \) is contained in the non-degenerate locus. This is an open substack since \( C \) is complete. Define the map

\[
(M_X \times \text{Sym} C)^{\ast} \to \mathcal{L}^+ X \times_{\mathcal{L}^+ G} \mathcal{L}^+ G
\]

over \( \text{Sym} C \) by sending \((f, D)\) to \((f|_{\tilde{C}'_D}, D)\). Here we are using the fact that an \( \mathcal{L}^+ G \)-torsor on an affine scheme \( S \) is the same as a \( G \)-torsor on \( \tilde{C}'_D \) by formal lifting.

Recall that we defined a partition \( \Theta \), or unordered multiset without zero, in \( c_{\tilde{X}} \), to mean an element of \( \text{Sym}^\infty(c_{\tilde{X}} - 0) \). To such a partition \( \Theta \), we have a corresponding locally closed subscheme \( \mathcal{L}_{\Theta} X \hookrightarrow \mathcal{L}^+ X \) by Proposition A.2.3. Then we can define \( M_X^{\Theta} \) to be the preimage of \( \mathcal{L}_{\Theta} X / \mathcal{L}^+ G \) under the map (A.2). One can check from the construction that this definition gives the description on \( k \)-points from \S 3.1.5. By base change \( M_X^{\Theta} \) is a locally closed subscheme of \( M_X \times C^{(\Theta)} \). In particular, \( M_X^{\Theta} \) is an algebraic stack locally of finite type over \( k \).

Lemma A.3.1. The natural map \( M_X^{\Theta} \to \mathcal{L}_{\Theta} X / \mathcal{L}^+ G \) is formally smooth.

Proof. Let \( S \to S' \) be a nilpotent thickening of affine schemes. Let \((f, D) \in M_X^{\Theta}(S)\). This maps to the point \((f|_{\tilde{C}'_D}, D) \in \mathcal{L}_{\Theta}^* X(S)\). Suppose that we have a lift of this point to \((\tilde{f}, D') \in \mathcal{L}_{\Theta}^* X(S')\), where \( D' \subseteq C \times S' \) is a relative effective Cartier divisor and \( \tilde{f} : \tilde{C}'_D \to X/G \) is equivalent to the datum of a \( G \)-bundle \( \tilde{\mathcal{P}}_G \) on \( \tilde{C}'_D \), and a section \( \sigma : \tilde{f} : \tilde{C}'_D \to X/G \). We would like to lift \((f, D)\) to an \( S' \)-point of \( M_X^{\Theta} \) that maps to \((\tilde{f}, D')\). The map \( f : C \times S \to X/G \) consists of the datum of the \( G \)-bundle \( \mathcal{P}_G \) on \( C \times S \) and a section \( \sigma : C \times S \to X^* \times G \mathcal{P}_G \) satisfies the condition that \( \sigma(C \times S - D) \subseteq X^* \times G \mathcal{P}_G = (H \backslash G) \times G \mathcal{P}_G \). The restriction \( \sigma|_{C \times S - D} \) gives a reduction of \( \mathcal{P}_G|_{C \times S - D} \cong G \times H \mathcal{P}_H \) to an \( H \)-bundle \( \mathcal{P}_H \) on \( C \times S - D \) such
that $\sigma|_{C \times S - D}$ identifies with the canonical section
\[
C \times S - D \cong H\\mathcal{P}_H \rightarrow (H\\mathcal{G})^H \times \mathcal{P}_H \cong (H\\mathcal{G})^G \times \mathcal{P}_G|_{C \times S - D}
\]
corresponding to $H1 \in H\mathcal{G}$.

The obstruction to lifting $\mathcal{P}_H$ to an $H$-bundle $\mathcal{P}'_H$ on $C \times S - D'$ is an element in $H^2(C \times S - D, \mathcal{H}_\mathcal{P}_H \otimes O_G I)$ where $I$ is the zero ideal of $S \hookrightarrow S'$ and $\mathcal{H}_\mathcal{P}_H$ denotes the quasi-coherent sheaf on $C \times S - D$ obtained by twisting the adjoint representation of $H$ by $\mathcal{P}_H$. This obstruction vanishes since $C \times S - D$ has relative dimension 1 over $S$ and we can compute cohomology over the Zariski site. Thus we obtained an $H$-bundle $\mathcal{P}'_H$ over $C \times S' - D'$. Let $\sigma' : C \times S' - D' \rightarrow X^G(G \times H\\mathcal{P}'_H)$ denote the corresponding section.

We know that after base change to $S$, there exists an isomorphism
\[
\tau : \mathcal{P}'_G|_{\mathcal{C}_D} \cong \mathcal{P}_G|_{\mathcal{C}_D} \cong (G \times H\\mathcal{P}'_H)|_{\mathcal{C}_D}
\]
such that $\tau \circ \sigma'|_{\mathcal{C}_D} = \sigma'|_{\mathcal{C}_D}$. This is equivalent to a section $\beta : \mathcal{C}_D \rightarrow \mathcal{P}'_H \times^H G \times^G \mathcal{P}'_G$ such that $\beta$ is sent under
\begin{equation}
(A.3)
\mathcal{P}'_H \times^G \mathcal{P}'_G \rightarrow (C \times S') \times X^G \mathcal{P}'_G
\end{equation}
to the restriction $\tau'|_{\mathcal{C}_D'}$. The map $(A.3)$ is smooth since $G \rightarrow X$ is smooth. The scheme $\mathcal{C}_D'$ is affine since $S'$ is affine and $D'$ is in the disjoint locus of $\text{Sym}C$. The zero ideal of $\mathcal{C}_D' \rightarrow \mathcal{C}_D'$ is still nilpotent, so by formal smoothness of $(A.3)$, we can lift $\beta$ to a section $\beta'$ that maps to $\tau'|_{\mathcal{C}_D'}$. Such a section $\beta'$ is equivalent to an isomorphism $\tau' : \mathcal{P}'_G|_{\mathcal{C}_D'} \cong (G \times H\\mathcal{P}'_H)|_{\mathcal{C}_D'}$ such that $\tau' \circ \sigma'|_{\mathcal{C}_D'} = \sigma'|_{\mathcal{C}_D'}$. By Beauville–Laszlo’s theorem (Lemma 3.7.7), the data $(\mathcal{P}'_G, \sigma'), (\mathcal{P}'_H, \sigma'), (\tau')$ descends to a map $f' : C \times S' \rightarrow X/G$. By construction, $(f', D')$ is an $S'$-point of $\mathcal{M}_X^G$ lifting $f$.

**Proof of Lemma 3.1.6.** Lemma A.3.1 and Proposition A.2.3 together imply that $\mathcal{M}_X^G$ is formally smooth over $k$. Since $\mathcal{M}_X^G$ is locally of finite type, it is therefore smooth over $k$.

We claim that the first projection $\text{pr}_1 : \mathcal{M}_X \times C^{(\tilde{\Theta})} \rightarrow \mathcal{M}_X$ induces a locally closed embedding $\mathcal{M}_X^G \hookrightarrow \mathcal{M}_X$. Let $Z \subset \mathcal{M}_X \times C^{(\tilde{\Theta})}$ denote the substack with $S$-points consisting of those $(f, D)$ such that $f^{-1}(X^*/G) \cap D = \emptyset$. Since $D$ is faithfully flat over $S$, the image of $f^{-1}(X^*/G) \cap D$ in $S$ is open. Therefore $Z$ is a closed substack of $\mathcal{M}_X \times C^{(\tilde{\Theta})}$. Since $\tilde{\Theta}$ is a multiset without zero, observe that $\mathcal{M}_X^G$ embeds into $Z$. Now $(f, D) \in Z(k)$ satisfies the property that the support of $D \in C^{(\tilde{\Theta})}$ is contained in the support of $C - f^{-1}(X^*/G)$. We deduce that $\text{pr}_1|_Z : Z \rightarrow \mathcal{M}_X$ is proper and quasi-finite, hence finite. On the other hand, $\text{pr}_1|_{\mathcal{M}_X^G}$ is injective on $k$-points, and $(\text{pr}_1|_Z)^{-1}(\text{pr}_1(\mathcal{M}_X^G)) = \mathcal{M}_X^G$. From this we deduce that $\text{pr}_1|_{\mathcal{M}_X^G}$ is a locally closed embedding.

**A.4. Generic-Hecke modifications.** We review the notion of generic-Hecke modifications between quasi-maps introduced in [GN10, §2.2], applied to our situation. We assume that $B$ acts simply transitively on $X^\circ$ and that $H$ is connected.

**A.4.1. Function-theoretic analog.** We explain the idea behind the generic-Hecke modifications at the level of sets: this construction appears in various places in the geometric Langlands program in the construction of Whittaker models, cf. [Gai15, §5.3.1].
We use the notation of §3.1.3. For any finite subset \( v \subset |C| \), let \( A^u = \prod_{v' \notin v} F_{v'} \), and similarly for \( \Omega^u, \Omega^v \). Then we can consider the set

\[(A.4) \quad G(A^u)/G(\Omega^u) \times H(A^u)/H(\Omega^u)\]

which maps to \( H(k)\backslash G(A)/G(\Omega) \) in two ways: (i) by projecting along the first factor to \( \ker(H(k) \to H(\Omega^u)) \backslash G(A^u)/G(\Omega^u) \subset H(k)\backslash G(A)/G(\Omega) \) and (ii) by projecting to

\[H(k)\backslash \left( G(A^u)/G(\Omega^u) \times H(A^u)/H(\Omega^u) \right) \subset H(k)\backslash G(A)/G(\Omega).\]

Every meromorphic quasimap (element of \( H(k)\backslash G(A)/G(\Omega) \)) belongs to the image of the second projection for some \( v \). If \( H \) is connected, then by weak approximation \( H(A^u) = H(k)H(\Omega^u) \) so every quasi-map also belongs to the image of the first projection. Thus the union of (A.4) over all finite subsets \( v \) defines a groupoid acting on the set of quasimaps.

A.4.2. We define the ind-stack \( \mathcal{H}_{H,M_X} \) of \textit{generic-Hecke modifications} to be the stack classifying data

\[(P^1_G, P^2_G, \sigma_1, \sigma_2; v, \tau)\]

where \( (P^i_G, \sigma_i) \in M_X, v \in \text{Sym } C \) is a divisor with support \( v \) contained in the non-degenerate locus \( \sigma_i^{-1}(X^G \times P^G_{v}) \) for both \( i = 1, 2 \) and \( \tau \) is an isomorphism of \( G \)-bundles

\[\tau : P^1_G|_{C-v} \cong P^2_G|_{C-v}\]

such that the following diagram commutes

\[
\begin{array}{ccc}
C - v & \xrightarrow{\sigma_1} & P^1_G \times X|_{C-v} \\
\downarrow{\sigma_2} & & \downarrow{\tau} \\
& P^2_G \times X|_{C-v}.
\end{array}
\]

Note that the definition only depends on the support of \( v \) and not its multiplicities.

We call a generic-Hecke modification \textit{trivial} if the isomorphism \( \tau \) extends to an isomorphism over all of \( C \). We have the natural projections

\[M_X \xleftarrow{h^u} \mathcal{H}_{H,M_X} \xrightarrow{h^\gamma} M_X,\]

and \( \mathcal{H}_{H,M_X} \to \text{Sym } C \). By definition, the generic-Hecke correspondence preserves the strata \( M^G_X \).

Define a \textit{smooth generic-Hecke correspondence} to be any stack \( U \) equipped with smooth maps

\[M_X \xleftarrow{h^u} U \xrightarrow{h^\gamma} M_X\]

such that there exists a map \( U \to \mathcal{H}_{H,M_X} \) such that the following diagram commutes

\[
\begin{array}{ccc}
M_X & \xleftarrow{h^u} & \mathcal{H}_{H,M_X} & \xrightarrow{h^\gamma} & M_X \\
\downarrow & & \downarrow \\
& M_X & \xleftarrow{h^u} & \mathcal{H}_{H,M_X} & \xrightarrow{h^\gamma} & M_X
\end{array}
\]

Call a smooth generic-Hecke correspondence \( U \) \textit{trivial} if the image of \( U \to \mathcal{H}_{H,M_X} \) consists of trivial generic-Hecke modifications.

Define a morphism of smooth generic-Hecke correspondences to be a map \( p : U_1 \to U_2 \) such that \( h^u_{U_2} \circ p = h^u_{U_1} \) and \( h^\gamma_{U_2} \circ p = h^\gamma_{U_1} \).
A.4.3. Fix $\tilde{\theta} \in \epsilon_X$. Recall that by definition $M_{X,v_0}^\theta$ is a substack of $M_X \times C$. For a fixed $v_0 \in |C|$, define $M_{X,v_0}^\theta := M_{X,v_0}^\theta \times_C v_0$ to be the based stratum consisting of maps $C \to X/G$ such that $C - v_0$ maps to $H/P$ and the $G$-valuation at $v_0$ is $\tilde{\theta}$. Observe that the generic-Hecke modifications preserve the substack $M_{X,v_0}^\theta$.

**Proposition A.4.4** ([GN10, Proposition 3.5.1]). If $H$ is connected, then all geometric points of $M_{X,v_0}^\theta \subset M_X$ are equivalent under the equivalence relation generated by the generic-Hecke correspondences.

The preimage of $C \subset \text{Sym} C$ in $H_{H,M_X}$ may be realized as the twisted product of an open substack of $M_X \times C$ with the affine Grassmannian $Gr_H$. From this it is not hard to deduce that all geometric points of $M_{X,v_0}^\theta$ are equivalent under smooth generic-Hecke correspondences.

A.4.5. Recall the $G$-Hecke action defined in Proposition 5.2.3. By construction, this action commutes with the generic $H$-Hecke modifications as an analog of the stratification by orbits of a group action. This will be the idea behind the proof of Proposition 3.1.7, together with the following fact:

**Lemma A.4.6.** The map $\text{act}_C : M_X \times Gr_{H,C} \to M_X \times C$ is equivariant with respect to the generic-Hecke modifications away from the marked point in $C$.

A.4.7. **Proof of Proposition 3.1.7.** Proposition A.4.4 allows us to consider the based strata with generic-Hecke modifications as an analog of the stratification by orbits of a group action. This will be the idea behind the proof of Proposition 3.1.7, together with the following fact:

**Theorem A.4.8** ([Kal05, Theorem 2]). Let $S$ be a smooth stratum in an algebraically stratified scheme of finite type over $k$. Then the subset of points in $S$ that do not satisfy Whitney’s condition $B$ form a constructible subset of dimension strictly lower than $\dim S$.

Thus if we show that any two points in a given stratum have neighborhoods in $M_X$ that are smooth locally isomorphic and compatible with the stratification, Theorem A.4.8 will imply that every point must satisfy Whitney’s condition B.

Fix a connected component of $M_{X,v_0}^\theta$ for some $\tilde{\theta} \in \epsilon_X$. Since Whitney’s condition B is local in the smooth topology, it suffices by Corollary 3.5.2 to show that every point in $Y^\lambda,\tilde{\theta}$ satisfies Whitney’s condition for all $\tilde{\lambda} \in \epsilon_X$. Now the graded factorization property of $Y$ allows us to reduce to the case where $\tilde{\Theta} = [\tilde{\theta}]$ is singleton. By Proposition 4.2.3, we may replace our curve $C$ with $A^1 = \mathbb{P}^1 - \infty$, i.e., $Y^\lambda = Y^\lambda(A^1)$. Now $A^1$ acts on itself by translation, which induces an $A^1$-action by automorphisms on $Y^\lambda(A^1)$. This action allows us to move the degenerate point of any $y \in Y^\lambda,\tilde{\theta}(A^1)$ to $v_0 = 0 \in A^1$, i.e., the map $y : A^1 \to X/B$ sends $A^1 - 0 \to X^*/B$ and the $G$-valuation at $v_0$ equals $\tilde{\theta}$. Thus we are reduced to showing that any point in $Y^\lambda,\tilde{\theta}$ with degenerate point at $v_0$ satisfies Whitney’s condition.

Embed $A^1 = \mathbb{P}^1 - \infty \subset \mathbb{P}^1$ so we also have an open embedding $Y^\lambda(A^1) \subset Y^\lambda(\mathbb{P}^1)$. Lemma 3.5.4 shows that $Y^\lambda(\mathbb{P}^1)$ is smooth locally isomorphic to $M_X = M_X(\mathbb{P}^1)$ in a way that preserves strata and degenerate points. Therefore we may reduce to checking that any point in $M_{X,v_0}^\theta$ satisfies Whitney’s condition B. Proposition A.4.4 implies that all such points are equivalent under smooth generic-Hecke correspondences (which preserve strata), so either they all satisfy or fail to satisfy Whitney’s condition. By Theorem A.4.8, we deduce that every point satisfies Whitney’s condition B.

The same argument as above also shows that the closure of any stratum in $M_X$ must equal a union of strata.
APPENDIX B. UNIVERSAL LOCAL ACYCLICITY

In this section, $k$ can be any perfect field. We recall the definition of universal local acyclicity as in [Del77]. Let $S$ be a scheme and $s$ a geometric point of $S$. We denote by $S_{(s)}$ the strict Henselisation of $S$ at $s$. We will formally write $t \to s$ if $t$ is a geometric point of $S_{(s)}$.

**Definition B.0.1.** Let $f : Y \to S$ be a morphism of schemes of finite type over $k$. An object $\mathcal{F} \in \mathcal{D}_c^b(Y)$ is called locally acyclic with respect to $f$ if for every geometric point $y$ of $Y$ and every specialisation $t \to f(y)$, the natural map $R\Gamma(Y_{(y)}, \mathcal{F}) \to R\Gamma(Y_{(y)} \times_{S_{(f(y))}} t, \mathcal{F})$ is an isomorphism.

It is called universally locally acyclic (ULA) if it is locally acyclic after arbitrary base change $S' \to S$.

We refer the reader to [Del77], [Zhu17, §A.2] for a review of the ULA property. In particular, the property is local in the smooth topology on the source and target (cf. [Zhu17, Theorem A.2.5]), meaning: Let $f : Y \to S$ be a morphism of finite type $k$-schemes and $\mathcal{F} \in \mathcal{D}_c^b(Y)$.

1. If $g : Y' \to Y$ is a smooth (resp. smooth and surjective) map, then $g^*(\mathcal{F}) \in \mathcal{D}_c^b(Y')$ is ULA with respect to $f \circ g : Y' \to S$ if (resp. if and only if) $\mathcal{F}$ is ULA with respect to $f : Y \to S$.
2. If $g : S \to S'$ is a smooth map and $\mathcal{F}$ is ULA with respect to $f : Y \to S$, then $\mathcal{F}$ is ULA with respect to $g \circ f : Y \to S'$.

Therefore it makes sense to extend the definition of ULA to morphisms between algebraic stacks of finite type over $k$. We continue to work with schemes in this appendix, but one can easily generalize the statements to stacks.

In [BG02, §5.1, Theorem B.2], the authors introduced an equivalent definition (Definition B.0.2 below) of locally acyclic complexes when the base $S$ is smooth. In this appendix we will prove some properties of ULA complexes when the base $S$ is possibly not smooth, following the arguments in the proof of [BG02, Theorem B.2], with the goal of proving Lemma 4.5.3.

First, we have the following reformulation of Definition B.0.1 by [BG02]: Let $j : S_0 \to S$ be a smooth locally closed subvariety and let $\mathcal{L}$ be a lisse sheaf on $S_0$. Consider the Cartesian diagram

$$
\begin{array}{ccc}
Y_0 & \xrightarrow{j_0} & S_0 \\
\downarrow{j'} & & \downarrow{j} \\
Y & \xrightarrow{f} & S
\end{array}
$$

By the $(j'^*, j_*)$-adjunction we have a natural map

$$
\mathcal{F} \otimes f^*(\mathcal{L}) \to j'_*(j^*(\mathcal{F}) \otimes f_0^*(\mathcal{L})).
$$

One observes that $\mathcal{F} \in \mathcal{D}_c^b(Y)$ is locally acyclic with respect to $f$ if and only if for all $S_0$ and $\mathcal{L}$ as above, the map (B.1) is an isomorphism.

Now let $\mathcal{G} \in \mathcal{D}_c^b(S)$ be arbitrary. We have a natural map

$$
f^*(\mathcal{G}) \otimes f^!(\mathcal{L}) \to f^1(\mathcal{G}),
$$

which comes by adjunction from the map

$$
f_!(f^*(\mathcal{G}) \otimes f^!(\mathcal{L})) \cong \mathcal{G} \otimes f_!(f^1(\mathcal{L})) \to \mathcal{G} \otimes \mathcal{L}.
$$

The map (B.2) induces a natural map

$$
\text{Hom}(\mathcal{F}, f^!(\mathcal{L})) \otimes f^*\mathcal{G} \to \text{Hom}(\mathcal{F}, f^!(\mathcal{L} \otimes f^*\mathcal{G})) \xrightarrow{(B.2)} \text{Hom}(\mathcal{F}, f^*\mathcal{G})
$$

where $\text{Hom}$ is the (derived) internal Hom.
Let $\mathbb{D}$ denote the duality functor. By Grothendieck’s six functor formalism, there is a functorial isomorphism
\begin{equation}
\mathbb{D}(\mathcal{F}_1 \otimes \mathcal{F}_2) \cong \text{Hom}(\mathcal{F}_1, \mathcal{F}_2), \quad \mathcal{F}_1, \mathcal{F}_2 \in D^b_c(Y)
\end{equation}
([SGA77, Exposé I, Proposition 1.11(c)]). Therefore we have $\text{Hom}(\mathcal{F}, f^! \mathcal{G}) \cong \mathbb{D}(\mathcal{F} \otimes f^* \mathcal{G})$.

Let $\mathcal{F}_1 \otimes^! \mathcal{F}_2 := \mathbb{D}(\mathcal{D} \mathcal{F}_1 \otimes \mathcal{D} \mathcal{F}_2)$ denote the conjugate of $\otimes$ by $\mathbb{D}$.

If $S$ is smooth, then $\text{Hom}(\mathcal{F}, f_!(\mathcal{L} \mathcal{G})) = \mathbb{D}(\mathcal{F})(-d)[-2d]$ where $d : \pi_0(S) \to \mathbb{Z}$ is the dimension. Then using (B.4), we deduce that the Verdier dual of (B.3) is a map
\begin{equation}
\mathcal{F} \otimes f^*(\mathcal{D} \mathcal{G}) \to \mathcal{F} \otimes f^!(\mathcal{D} \mathcal{G})(d)[2d].
\end{equation}

Then [BG02, Theorem B.2] showed that Definition B.0.1 is equivalent to the following:

**Theorem B.0.2.** Let $f : Y \to S$ be a morphism of schemes of finite type over $k$ where $S$ is smooth. An object $\mathcal{F} \in D^b_c(Y)$ is locally acyclic with respect to $f$ if and only if (B.5) is an isomorphism for every $\mathcal{G} \in D^b_c(S)$.

We now use Theorem B.0.2 to deduce several properties of ULA complexes with respect to morphisms $f : Y \to S$ where the base $S$ is not necessarily smooth. These properties are presumably known to experts\(^{24}\) but we provide proofs as they do not seem to appear in the literature.

**Proposition B.0.3.** If $\mathcal{F}$ is ULA with respect to $f : Y \to S$, then for every $\mathcal{G} \in D^b_c(S)$, the natural map (B.3) is an isomorphism
\begin{equation}
\text{Hom}(\mathcal{F}, f^! \mathcal{L} \mathcal{G}) \otimes f^* \mathcal{G} \cong \text{Hom}(\mathcal{F}, f^\circ \mathcal{G}).
\end{equation}

**Proof.** We may assume $S$ is reduced and hence generically smooth. Let $j : S_0 \hookrightarrow S$ be a smooth open dense subvariety of $S$ such that $j^* \mathcal{G}$ has lisse cohomology sheaves. Let $i : S_1 \hookrightarrow S$ denote the complementary closed embedding. Let $j' : Y_0 \hookrightarrow Y$ and $i' : Y_1 \hookrightarrow Y$ denote the corresponding embeddings after base change to $Y$ and $f_1 : Y_1 \to S_1$ the projection. The $j_! j^! \to 1 \to i_* i^*$ distinguished triangle applied to $(\mathcal{L} \mathcal{G})_S$ and $\mathcal{G}$ gives a map of distinguished triangles
\begin{equation}
\begin{array}{ccc}
\text{Hom}(\mathcal{F}, f_! j_!(\mathcal{L} \mathcal{G})_S) \otimes f^* \mathcal{G} & \longrightarrow & \text{Hom}(\mathcal{F}, f^! \mathcal{L} \mathcal{G}) \otimes f^* \mathcal{G} \\
\downarrow & & \downarrow \\
\text{Hom}(\mathcal{F}, f'_! j'_! \mathcal{G}) & \longrightarrow & \text{Hom}(\mathcal{F}, f^! \mathcal{G})
\end{array}
\end{equation}

We will show that the left and right vertical arrows are isomorphisms, which implies the middle arrow is also an isomorphism.

By (B.4) we have $\text{Hom}(\mathcal{F}, f_! j_!(\mathcal{L} \mathcal{G})_S_0) \cong \mathbb{D}(\mathcal{F} \otimes f^* j_*(\mathcal{L} \mathcal{G})_S_0(d_0)[2d_0])$, where we have used that $S_0$ is smooth of dimension $d_0 : \pi_0(S_0) \to \mathbb{Z}$. Therefore the isomorphism of (B.1) gives
\begin{equation}
\text{Hom}(\mathcal{F}, f_! j_!(\mathcal{L} \mathcal{G})_S_0) \otimes f^* \mathcal{G} \cong j'_! \left( \mathbb{D}(j^* \mathcal{F}) \otimes f_0^* (j^* \mathcal{G}) \right)(-d_0)[-2d_0].
\end{equation}

Since $\mathcal{F}$ is ULA, $\mathbb{D}(j^* \mathcal{F})$ is ULA with respect to $f_0 : Y_0 \to S_0$ where $S_0$ is smooth. Thus using Theorem B.0.2, we have a canonical isomorphism
\begin{equation}
\mathbb{D}(j^* \mathcal{F}) \otimes f_0^* (j^* \mathcal{G})(-d_0)[-2d_0] \cong \mathbb{D}(j^* \mathcal{F}) \otimes f_0^* (j^* \mathcal{G}) \cong j^* \text{Hom}(\mathcal{F}, f^\circ \mathcal{G}),
\end{equation}

\(^{24}\)We learned of the statements from [KHW17, Theorem 4.6.3], which lives in the more nuanced setting of $p$-adic geometry.
where we are using (B.4) in the second isomorphism. To summarize, we have a canonical isomorphism $\text{Hom}(\mathcal{F}, f^! i_!(\mathbb{Q}_S)) \otimes f^* \mathcal{G} \cong j_! j^* \text{Hom}(\mathcal{F}, f^! \mathcal{G})$. On the other hand, since $j^* \mathcal{G}$ is lisse, the same argument as above using the isomorphism (B.3) gives an isomorphism

$$\text{Hom}(\mathcal{F}, f^! j_!(\mathcal{G})) \cong j^! \text{Hom}(j^* \mathcal{F}, f^! j_!(\mathcal{G})) \cong j^* j_! \text{Hom}(\mathcal{F}, f^! \mathcal{G}).$$

Thus we have shown that the left vertical arrow in (B.6) is an isomorphism.

For the right vertical arrow, we have a natural isomorphism

$$\text{Hom}(\mathcal{F}, i^! t_!(\mathbb{Q}_S)) \otimes f^* \mathcal{G} \cong i^! \text{Hom}(i^* \mathcal{F}, t_!(\mathbb{Q}_S))$$

by adjunction and projection formula. Since $\mathcal{F}$ is ULA, after base change $i^* \mathcal{F}$ is ULA with respect to $f$. Hence by noetherian induction on $\text{dim}(S)$ we may assume that we have a canonical isomorphism

$$\text{Hom}(i^* \mathcal{F}, t_!(\mathbb{Q}_S)) \cong i^! \text{Hom}(i^* \mathcal{F}, t_!(\mathbb{Q}_S)) \cong \text{Hom}(\mathcal{F}, f^! i^* \mathcal{G}),$$

which is the isomorphism of the right vertical arrow in (B.6). \qed

Now consider a Cartesian diagram of schemes of finite type over $k$:

$$\begin{array}{ccc}
Y' & \xrightarrow{f'} & S' \\
\downarrow{g'} & & \downarrow{g} \\
Y & \xrightarrow{f} & S
\end{array}$$

(B.8)

For $\mathcal{F} \in \mathcal{D}_b(Y)$, there is a natural map

$$(g')^* \text{Hom}(\mathcal{F}, f^! \mathbb{Q}_S) \rightarrow \text{Hom}((g')^* \mathcal{F}, (f')^! \mathbb{Q}_S)$$

which comes by the $(g^*, g^*_i)$-adjunction from the map

$$\text{Hom}(\mathcal{F}, f^! \mathbb{Q}_S) \rightarrow \text{Hom}(\mathcal{F}, f^! g_* g^* \mathbb{Q}_S) \cong \text{Hom}(\mathcal{F}, g_! (f')^! \mathbb{Q}_S) \cong g_* \text{Hom}((g')^* \mathcal{F}, (f')^! \mathbb{Q}_S),$$

where we used proper base change in the second arrow.

Proposition B.0.4. In the setup above, if $\mathcal{F}$ is ULA with respect to $f$, then the natural map (B.9) is an isomorphism

$$(g')^* \text{Hom}(\mathcal{F}, f^! \mathbb{Q}_S) \cong \text{Hom}((g')^* \mathcal{F}, (f')^! \mathbb{Q}_S).$$

Proof. The assertion is Zariski-local on $S'$, so we may assume that $S, S'$ are affine and $g$ factors as $S' \xrightarrow{i'} \mathbb{A}^n \times S \xrightarrow{pr_2} S$ where $i$ is a closed embedding. The isomorphism of (B.9) when $g$ is smooth follows from the isomorphism

$$(g')^! \text{Hom}(\mathcal{F}, f^! \mathbb{Q}_S) \cong \text{Hom}((g')^! \mathcal{F}, (g')^! f^! \mathbb{Q}_S),$$

which always holds in the six functor formalism. Therefore after base change along $pr_2 : \mathbb{A}^n \times S \rightarrow S$, we may assume that $g : S' \hookrightarrow S$ is a closed embedding and $S', S$ are reduced. The open complement $S - S'$ is nonempty (otherwise we are done) so there exists a smooth dense open subvariety $j : S_0 \hookrightarrow S$ inside $S - S'$. Let $i : S_1 \hookrightarrow S$ denote the complement of $S_0$, so $g$ factors as $S' \xrightarrow{g_1} S_1 \xrightarrow{i} S$. Let $i', j', g'_1$ denote the preimages in $Y$ and $f_i : Y_i \rightarrow S_i$ the base change of $f$. The $j j' \rightarrow 1 \rightarrow i, i'$ distinguished triangle induces a distinguished triangle

$$(g')^* \text{Hom}(\mathcal{F}, f^! j_!(\mathbb{Q}_S)) \rightarrow (g')^* \text{Hom}(\mathcal{F}, f^! \mathbb{Q}_S) \rightarrow (g'_1)^* \text{Hom}(i^* \mathcal{F}, i^! \mathbb{Q}_S)$$

Just as in the proof of Proposition B.0.3, (B.7), we have a canonical isomorphism

$$\text{Hom}(\mathcal{F}, f^! j_!(\mathbb{Q}_S)) \cong j'_! j''_!(\mathcal{F})(-d_0)[-2d_0].$$
Therefore the leftmost term in the distinguished triangle vanishes, and hence the second arrow is an isomorphism. Now $i^*\mathcal{F}$ is ULA with respect to $Y_1 \to S_1$, so by induction on the codimension of $S'$ in $S$, we conclude that

$$(g')^*\text{Hom}(\mathcal{F}, f^*\mathcal{Q}_\ell) \cong (g_1')^*\text{Hom}(i^*\mathcal{F}, f_1^*\mathcal{Q}_\ell) \cong \text{Hom}(g^*\mathcal{F}, f^*\mathcal{Q}_\ell),$$

and this isomorphism coincides with (B.9). \hfill \Box

Again in the setting of the diagram (B.8), given $\mathcal{F} \in D^b_0(Y), \mathcal{F}' \in D^b_0(S')$ we let

$$\mathcal{F} \boxtimes \mathcal{F}' := (g')^*\mathcal{F} \otimes (f')^*\mathcal{F}'(-\frac{d}{2})[-d] \in D^b_0(Y')$$

where $d : \pi_0(S) \to \mathbb{Z}$ denotes the dimension of each connected component of $S$.

**Corollary B.0.5.** In the diagram (B.8), assume that $S$ is rationally smooth, i.e., the dualizing complex of $S$ is isomorphic to $\mathcal{Q}_\ell[2d]$. Let $\mathcal{F} \in D^b_0(Y), \mathcal{F}' \in D^b_0(S')$ and assume that $\mathcal{F}$ is ULA with respect to $f : Y \to S$. Then there is a natural isomorphism

$$D(\mathcal{F} \boxtimes \mathcal{F}') \cong D(\mathcal{F} \boxtimes S).$$

**Proof.** We have the sequence of isomorphisms

$$D(\mathcal{F} \boxtimes \mathcal{F}') = (g')^*(\mathcal{F}) \otimes (f')^*(\mathcal{F})'(-\frac{d}{2})[-d]$$

$$= (g')^*\text{Hom}(\mathcal{F}, f^*\mathcal{Q}_\ell(\frac{d}{2})[d]) \otimes f^*(\mathcal{F})'$$

$$\cong \text{Hom}((g')^*\mathcal{F}, (f')^*\mathcal{Q}_\ell(\frac{d}{2})[d]) \otimes f^*(\mathcal{F})' \quad \text{(Prop. B.0.4)}$$

$$\cong \text{Hom}((g')^*\mathcal{F}, (f')^*\mathcal{Q}_\ell(\frac{d}{2})[d]) \otimes f^*(\mathcal{F})' \quad \text{(Prop. B.0.3)}$$

$$\cong D((g')^*\mathcal{F} \otimes (f')^*\mathcal{F}'(-\frac{d}{2})[-d]) \quad \text{(B.4)}$$

$$= D(\mathcal{F} \boxtimes \mathcal{F}')$$

where we are applying Proposition B.0.3 to $(g')^*\mathcal{F}$, which is ULA with respect to $f' : Y' \to S'$.

\hfill \Box

**Lemma B.0.6.** In the diagram (B.8), assume that $S$ is smooth. Let $\mathcal{F} \in D_0^b(Y), \mathcal{F}' \in D_0^b(S')$ and assume that $\mathcal{F}$ is ULA with respect to $f : Y \to S$. If $\mathcal{F} \in pD_{\leq 0}(Y)$ and $\mathcal{F}' \in pD_{\leq 0}(S')$, then (B.10)

$$\mathcal{F} \boxtimes \mathcal{F}' = (g')^*\mathcal{F} \otimes (f')^*\mathcal{F}' \in pD_{\leq 0}(Y').$$

**Proof.** By taking open neighborhoods of $S$ and $S'$, we may assume that $g$ factors as $S' \hookrightarrow \mathbb{A}^n \times S \xrightarrow{pr_2} S$ where $S' \hookrightarrow \mathbb{A}^n \times S$ is a closed embedding. Replacing $\mathcal{F}$ and $S$ with $pr_2^*(\mathcal{F})(\frac{d}{2})[u]$ and $\mathbb{A}^n \times S$, respectively, we reduce to the case when $g$ is a closed embedding.

By decomposing $\mathcal{F}'$ in the derived category with respect to a smooth stratification of $S'$, we may assume that $g : S' \hookrightarrow S$ is a smooth locally closed embedding and $\mathcal{F}'$ has lisse (usual) cohomology sheaves. If $\dim(S') < \dim(S)$, there exists an open $U \subset S$ and a smooth function $u : U \to \mathbb{A}^1$ such that $U \cap S' \subset u^{-1}(0)$. By induction on $\dim(S)$, we assume that (B.10) holds when $\ast$-restricted to $S - U$, so we can replace $S$ with $U$. Then we have $S' \hookrightarrow S_0 \hookrightarrow S$, where $S_0 = u^{-1}(0)$ is smooth of dimension $\dim(S) - 1$ and $i$ is a closed embedding. Now $\mathcal{F}$ is ULA with respect to $u \circ f : S \to \mathbb{A}^1$, so the isomorphism (B.5) implies that we have a natural isomorphism

$$i^*\mathcal{F}(-\frac{1}{2})[-1] \cong i^*\mathcal{F}(\frac{1}{2})[1]$$

where $i'$ is the base change of $i$. Since $i^*$ has cohomological amplitude $[-1, 0]$ while $i^!$ has cohomological amplitude $[0, 1]$ ([BBDG18, Corollaire 4.1.10]) we conclude that $i^*\mathcal{F}(-\frac{1}{2})[-1] \in D(\mathcal{F}')$.

Therefore, $\mathcal{F} \boxtimes \mathcal{F}' = (g')^*\mathcal{F} \otimes (f')^*\mathcal{F}' \in pD_{\leq 0}(Y')$. \hfill \Box
$p\mathcal{D} \leq 0(Y \times S S_0)$. Since $g : S' \to S$ factors through $S_0$, we can replace $S$ by $S_0$ (without changing $S'$). Continuing in this way, we reduce to the case where $\dim(S') = \dim(S)$. Now $\mathcal{F}'$ has usual cohomology sheaves only in degrees $\leq -\dim(S)$, so (B.10) holds.

Finally, we present the proof of Lemma 4.5.3.

Proof. Let $Y_0' := Y_0 \times S S'$ denote the open substack of $Y' = Y \times S S'$. The uniqueness property of intermediate extensions implies that the lemma amounts to showing:

(i) The $*$-restriction of $IC_Y \boxtimes_S IC_{S'}$ to $Y' - Y_0'$ lives in $p\mathcal{D} < 0(Y' - Y_0')$.
(ii) The $!$-restriction of $IC_Y \boxtimes_S IC_{S'}$ to $Y' - Y_0'$ lives in $p\mathcal{D} > 0(Y' - Y_0')$.
(iii) $IC_{Y_0} \boxtimes S IC_{S'} \cong IC_{Y_0'}$.

Assertion (iii) is immediate from smoothness of $f \circ j : Y_0 \to S$. The other assertions are local in the smooth topology, so we may assume that all stacks are reduced schemes. Corollary B.0.5 implies that $IC_Y \boxtimes_S IC_{S'}$ is Verdier self-dual, so it suffices to check the first assertion. Let $i : Y - Y_0 \hookrightarrow Y$ denote the closed embedding complementary to $j$ and let $i' : Y' - Y_0' \hookrightarrow Y'$ denote its base change. We have a distinguished triangle

$$j_!(IC_{Y_0}) \to IC_Y \to i_* i'^*(IC_Y).$$

Since $j_!(IC_{Y_0})$ and $IC_Y$ are both assumed to be ULA with respect to $f$, it follows that $i_* i'^*(IC_Y)$ is also ULA with respect to $f$. On the other hand, by proper base change and projection formula, we have a natural isomorphism

$$i_* i'^*(IC_Y) \boxtimes_S IC_{S'} \cong i'_* i'^*(IC_Y \boxtimes_S IC_{S'}),$$

so it suffices to show that the left hand side lives in strictly negative perverse cohomological degrees. By definition of $IC_Y$, we know that $i_* i'^*(IC_Y) \in p\mathcal{D} < 0(Y)$. Therefore assertion (i) follows from Lemma B.0.6 with $\mathcal{F} = i_* i'^*(IC_Y)(-\frac{1}{2})[-1]$ and $\mathcal{F}' = IC_{S'}$. □
